## CRYPTOSYSTEMS

This module contains base classes for various cryptosystems, including symmetric key and public-key cryptosystems. The classes defined in this module should not be called directly. It is the responsibility of child classes to implement specific cryptosystems. Take for example the Hill or matrix cryptosystem as implemented in *HillCryptosystem*. It is a symmetric key cipher so *HillCryptosystem* is a child class of *SymmetricKeyCryptosystem*, which in turn is a child class of *Cryptosystem*. The following diagram shows the inheritance relationship of particular cryptosystems:

**class** sage.crypto.cryptosystem.**Cryptosystem**(plaintext\_space, ciphertext\_space, key\_space, block\_length=1, period=None)

Bases: Parent, Set\_generic

A base cryptosystem class. This is meant to be extended by other specialized child classes that implement specific cryptosystems. A cryptosystem is a pair of maps

$$E : \mathcal{K} \rightarrow \text{Hom}(\mathcal{M}, \mathcal{C})$$

$$D : \mathcal{K} \rightarrow \text{Hom}(\mathcal{C}, \mathcal{M})$$

where  $\mathcal{K}$  is the key space,  $\mathcal{M}$  is the plaintext or message space, and  $\mathcal{C}$  is the ciphertext space. In many instances  $\mathcal{M} = \mathcal{C}$  and the images will lie in  $\text{Aut}(\mathcal{M})$ . An element of the image of  $E$  is called a cipher.

We may assume that  $E$  and  $D$  are injective, hence identify a key  $K$  in  $\mathcal{K}$  with its image  $E_K := E(K)$  in  $\text{Hom}(\mathcal{M}, \mathcal{C})$ .

The cryptosystem has the property that for every encryption key  $K_1$  there is a decryption key  $K_2$  such that  $D_{K_2} \circ E_{K_1}$ . A cryptosystem with the property that  $K := K_2 = K_1$ , is called a symmetric cryptosystem. Otherwise, if the key  $K_2 \neq K_1$ , nor is  $K_2$  easily derived from  $K_1$ , we call the cryptosystem asymmetric or public key. In that case,  $K_1$  is called the public key and  $K_2$  is called the private key.

INPUT:

- plaintext\_space – the plaintext alphabet.
- ciphertext\_space – the ciphertext alphabet.

- `key_space` – the key alphabet.
- `block_length` – (default: 1) the block length.
- `period` – (default: None) the period.

EXAMPLES:

Various classical cryptosystems:

```
sage: ShiftCryptosystem(AlphabeticStrings())
Shift cryptosystem on Free alphabetic string monoid on A-Z
sage: SubstitutionCryptosystem(HexadecimalStrings())
Substitution cryptosystem on Free hexadecimal string monoid
sage: HillCryptosystem(BinaryStrings(), 3)
Hill cryptosystem on Free binary string monoid of block length 3
sage: TranspositionCryptosystem(OctalStrings(), 5)
Transposition cryptosystem on Free octal string monoid of block length 5
sage: VigenereCryptosystem(Radix64Strings(), 7)
Vigenere cryptosystem on Free radix 64 string monoid of period 7
```

### `block_length()`

Return the block length of this cryptosystem. For some cryptosystems this is not relevant, in which case the block length defaults to 1.

EXAMPLES:

The block lengths of various classical cryptosystems:

```
sage: ShiftCryptosystem(AlphabeticStrings()).block_length()
1
sage: SubstitutionCryptosystem(HexadecimalStrings()).block_length()
1
sage: HillCryptosystem(BinaryStrings(), 3).block_length()
3
sage: TranspositionCryptosystem(OctalStrings(), 5).block_length()
5
sage: VigenereCryptosystem(Radix64Strings(), 7).block_length()
1
```

### `cipher_codomain()`

Return the alphabet used by this cryptosystem for encoding ciphertexts. This is the same as the ciphertext space.

EXAMPLES:

The cipher codomains, or ciphertext spaces, of various classical cryptosystems:

```
sage: ShiftCryptosystem(AlphabeticStrings()).cipher_codomain()
Free alphabetic string monoid on A-Z
sage: SubstitutionCryptosystem(HexadecimalStrings()).cipher_codomain()
Free hexadecimal string monoid
sage: HillCryptosystem(BinaryStrings(), 3).cipher_codomain()
Free binary string monoid
sage: TranspositionCryptosystem(OctalStrings(), 5).cipher_codomain()
Free octal string monoid
sage: VigenereCryptosystem(Radix64Strings(), 7).cipher_codomain()
Free radix 64 string monoid
```

**cipher\_domain()**

Return the alphabet used by this cryptosystem for encoding plaintexts. This is the same as the plaintext space.

EXAMPLES:

The cipher domains, or plaintext spaces, of various classical cryptosystems:

```
sage: ShiftCryptosystem(AlphabeticStrings()).cipher_domain()
Free alphabetic string monoid on A-Z
sage: SubstitutionCryptosystem(HexadecimalStrings()).cipher_domain()
Free hexadecimal string monoid
sage: HillCryptosystem(BinaryStrings(), 3).cipher_domain()
Free binary string monoid
sage: TranspositionCryptosystem(OctalStrings(), 5).cipher_domain()
Free octal string monoid
sage: VigenereCryptosystem(Radix64Strings(), 7).cipher_domain()
Free radix 64 string monoid
```

**ciphertext\_space()**

Return the ciphertext alphabet of this cryptosystem.

EXAMPLES:

The ciphertext spaces of various classical cryptosystems:

```
sage: ShiftCryptosystem(AlphabeticStrings()).ciphertext_space()
Free alphabetic string monoid on A-Z
sage: SubstitutionCryptosystem(HexadecimalStrings()).ciphertext_space()
Free hexadecimal string monoid
sage: HillCryptosystem(BinaryStrings(), 3).ciphertext_space()
Free binary string monoid
sage: TranspositionCryptosystem(OctalStrings(), 5).ciphertext_space()
Free octal string monoid
sage: VigenereCryptosystem(Radix64Strings(), 7).ciphertext_space()
Free radix 64 string monoid
```

**key\_space()**

Return the alphabet used by this cryptosystem for encoding keys.

EXAMPLES:

The key spaces of various classical cryptosystems:

```
sage: ShiftCryptosystem(AlphabeticStrings()).key_space()
Ring of integers modulo 26
sage: SubstitutionCryptosystem(HexadecimalStrings()).key_space()
Free hexadecimal string monoid
sage: HillCryptosystem(BinaryStrings(), 3).key_space()
Full MatrixSpace of 3 by 3 dense matrices over Ring of integers modulo 2
sage: TranspositionCryptosystem(OctalStrings(), 5).key_space()
Symmetric group of order 5! as a permutation group
sage: VigenereCryptosystem(Radix64Strings(), 7).key_space()
Free radix 64 string monoid
```

**period()**

**plaintext\_space()**

Return the plaintext alphabet of this cryptosystem.

EXAMPLES:

The plaintext spaces of various classical cryptosystems:

```

sage: ShiftCryptosystem(AlphabeticStrings()).plaintext_space()
Free alphabetic string monoid on A-Z
sage: SubstitutionCryptosystem(HexadecimalStrings()).plaintext_space()
Free hexadecimal string monoid
sage: HillCryptosystem(BinaryStrings(), 3).plaintext_space()
Free binary string monoid
sage: TranspositionCryptosystem(OctalStrings(), 5).plaintext_space()
Free octal string monoid
sage: VigenereCryptosystem(Radix64Strings(), 7).plaintext_space()
Free radix 64 string monoid
    
```

**class** sage.crypto.cryptosystem.**PublicKeyCryptosystem**(*plaintext\_space, ciphertext\_space, key\_space, block\_length=1, period=None*)

Bases: *Cryptosystem*

The base class for asymmetric or public-key cryptosystems.

**class** sage.crypto.cryptosystem.**SymmetricKeyCryptosystem**(*plaintext\_space, ciphertext\_space, key\_space, block\_length=1, period=None*)

Bases: *Cryptosystem*

The base class for symmetric key, or secret key, cryptosystems.

**alphabet\_size()**

Return the number of elements in the alphabet of this cryptosystem. This only applies to any cryptosystem whose plaintext and ciphertext spaces are the same alphabet.

EXAMPLES:

```

sage: ShiftCryptosystem(AlphabeticStrings()).alphabet_size()
26
sage: ShiftCryptosystem(BinaryStrings()).alphabet_size()
2
sage: ShiftCryptosystem(HexadecimalStrings()).alphabet_size()
16
sage: SubstitutionCryptosystem(OctalStrings()).alphabet_size()
8
sage: SubstitutionCryptosystem(Radix64Strings()).alphabet_size()
64
    
```

## CIPHERS

**class** sage.crypto.cipher.**Cipher**(*parent, key*)

Bases: [Element](#)

Cipher class

**codomain**()

**domain**()

**key**()

**class** sage.crypto.cipher.**PublicKeyCipher**(*parent, key, public=True*)

Bases: [Cipher](#)

Public key cipher class

**class** sage.crypto.cipher.**SymmetricKeyCipher**(*parent, key*)

Bases: [Cipher](#)

Symmetric key cipher class

## CLASSICAL CRYPTOSYSTEMS

A convenient user interface to various classical ciphers. These include:

- affine cipher; see *AffineCryptosystem*
- Hill or matrix cipher; see *HillCryptosystem*
- shift cipher; see *ShiftCryptosystem*
- substitution cipher; see *SubstitutionCryptosystem*
- transposition cipher; see *TranspositionCryptosystem*
- Vigenere cipher; see *VigenereCryptosystem*

These classical cryptosystems support alphabets such as:

- the capital letters of the English alphabet; see `AlphabeticStrings()`
- the hexadecimal number system; see `HexadecimalStrings()`
- the binary number system; see `BinaryStrings()`
- the octal number system; see `OctalStrings()`
- the radix-64 number system; see `Radix64Strings()`

AUTHORS:

- David Kohel (2007): initial version with the Hill, substitution, transposition, and Vigenere cryptosystems.
- Minh Van Nguyen (2009-08): shift cipher, affine cipher

**class** `sage.crypto.classical.AffineCryptosystem(A)`

Bases: *SymmetricKeyCryptosystem*

Create an affine cryptosystem.

Let  $A = \{a_0, a_1, a_2, \dots, a_{n-1}\}$  be a non-empty alphabet consisting of  $n$  unique elements. Define a mapping  $f : A \rightarrow \mathbf{Z}/n\mathbf{Z}$  from the alphabet  $A$  to the set  $\mathbf{Z}/n\mathbf{Z}$  of integers modulo  $n$ , given by  $f(a_i) = i$ . Thus we can identify each element of the alphabet  $A$  with a unique integer  $0 \leq i < n$ . A key of the affine cipher is an ordered pair of integers  $(a, b) \in \mathbf{Z}/n\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$  such that  $\gcd(a, n) = 1$ . Therefore the key space is  $\mathbf{Z}/n\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$ . Since we assume that  $A$  does not have repeated elements, the mapping  $f : A \rightarrow \mathbf{Z}/n\mathbf{Z}$  is bijective. Encryption and decryption functions are both affine functions. Let  $(a, b)$  be a secret key, i.e. an element of the key space, and let  $p$  be a plaintext character and consequently  $p \in \mathbf{Z}/n\mathbf{Z}$ . Then the ciphertext character  $c$  corresponding to  $p$  is given by

$$c \equiv ap + b \pmod{n}$$

Similarly, given a ciphertext character  $c \in \mathbf{Z}/n\mathbf{Z}$  and a secret key  $(a, b)$ , we can recover the corresponding plaintext character as follows:

$$p \equiv a^{-1}(c - b) \pmod{n}$$

where  $a^{-1}$  is the inverse of  $a$  modulo  $n$ . Use the bijection  $f : A \rightarrow \mathbf{Z}/n\mathbf{Z}$  to convert  $c$  and  $p$  back to elements of the alphabet  $A$ . Currently, only the following alphabet is supported for the affine cipher:

- capital letters of the English alphabet as implemented in `AlphabeticStrings()`

EXAMPLES:

Encryption and decryption over the capital letters of the English alphabet:

```
sage: A = AffineCryptosystem(AlphabeticStrings()); A
Affine cryptosystem on Free alphabetic string monoid on A-Z
sage: P = A.encoding("The affine cryptosystem generalizes the shift cipher.")
sage: P
THEAFFINECRYPTOSYSTEMGENERALIZESTHESHIFTCIPHER
sage: a, b = (9, 13)
sage: C = A.enciphering(a, b, P); C
CYXNGGHAXFKVSCJTVTCXRPXAXKNIHEXTCYXYHGC FHSYXK
sage: A.deciphering(a, b, C)
THEAFFINECRYPTOSYSTEMGENERALIZESTHESHIFTCIPHER
sage: A.deciphering(a, b, C) == P
True
```

We can also use functional notation to work through the previous example:

```
sage: A = AffineCryptosystem(AlphabeticStrings()); A
Affine cryptosystem on Free alphabetic string monoid on A-Z
sage: P = A.encoding("The affine cryptosystem generalizes the shift cipher.")
sage: P
THEAFFINECRYPTOSYSTEMGENERALIZESTHESHIFTCIPHER
sage: a, b = (9, 13)
sage: E = A(a, b); E
Affine cipher on Free alphabetic string monoid on A-Z
sage: C = E(P); C
CYXNGGHAXFKVSCJTVTCXRPXAXKNIHEXTCYXYHGC FHSYXK
sage: aInv, bInv = A.inverse_key(a, b)
sage: D = A(aInv, bInv); D
Affine cipher on Free alphabetic string monoid on A-Z
sage: D(C)
THEAFFINECRYPTOSYSTEMGENERALIZESTHESHIFTCIPHER
sage: D(C) == P
True
sage: D(C) == P == D(E(P))
True
```

Encrypting the ciphertext with the inverse key also produces the plaintext:

```
sage: A = AffineCryptosystem(AlphabeticStrings())
sage: P = A.encoding("Encrypt with inverse key.")
sage: a, b = (11, 8)
sage: C = A.enciphering(a, b, P)
sage: P; C
```

(continues on next page)

(continued from previous page)

```

ENCRYPTWITHINVERSEKEY
AVENMRJQSJHSVFANYAOAM
sage: aInv, bInv = A.inverse_key(a, b)
sage: A.enciphering(aInv, bInv, C)
ENCRYPTWITHINVERSEKEY
sage: A.enciphering(aInv, bInv, C) == P
True

```

For a secret key  $(a, b) \in \mathbf{Z}/n\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$ , if  $a = 1$  then any affine cryptosystem with key  $(1, b)$  for any  $b \in \mathbf{Z}/n\mathbf{Z}$  is a shift cryptosystem. Here is how we can create a Caesar cipher using an affine cipher:

```

sage: caesar = AffineCryptosystem(AlphabeticStrings())
sage: a, b = (1, 3)
sage: P = caesar.encoding("abcdef"); P
ABCDEF
sage: C = caesar.enciphering(a, b, P); C
DEFGHI
sage: caesar.deciphering(a, b, C) == P
True

```

Any affine cipher with keys of the form  $(a, 0) \in \mathbf{Z}/n\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$  is called a decimation cipher on the Roman alphabet, or decimation cipher for short:

```

sage: A = AffineCryptosystem(AlphabeticStrings())
sage: P = A.encoding("A decimation cipher is a specialized affine cipher.")
sage: a, b = (17, 0)
sage: C = A.enciphering(a, b, P)
sage: P; C
ADECIMATIONCIPHERISASPECIALIZEDAFFINECIPHER
AZQIGWALGENIGVPGDGAUVQIGAFGJQZAHHGNGQIGVPQD
sage: A.deciphering(a, b, C) == P
True

```

Generate a random key for encryption and decryption:

```

sage: A = AffineCryptosystem(AlphabeticStrings())
sage: P = A.encoding("An affine cipher with a random key.")
sage: a, b = A.random_key()
sage: C = A.enciphering(a, b, P)
sage: A.deciphering(a, b, C) == P
True

```

#### REFERENCES:

- [Sti2006]

#### **brute\_force**(*C*, *ranking*='none')

Attempt a brute force cryptanalysis of the ciphertext *C*.

#### INPUT:

- *C* – A ciphertext over one of the supported alphabets of this affine cryptosystem. See the class [AffineCryptosystem](#) for documentation on the supported alphabets.
- *ranking* – (default "none") the method to use for ranking all possible keys. If *ranking*="none", then do not use any ranking function. The following ranking functions are supported:

- "chi\_square" - the chi-square ranking function as implemented in the method `rank_by_chi_square()`.
- "squared\_differences" - the squared differences ranking function as implemented in the method `rank_by_squared_differences()`.

OUTPUT:

- All the possible plaintext sequences corresponding to the ciphertext C. This method effectively uses all the possible keys in this affine cryptosystem to decrypt C. The method is also referred to as exhaustive key search. The output is a dictionary of key, candidate decipherment pairs.

EXAMPLES:

Cryptanalyze using all possible keys with the option `ranking="none"`:

```
sage: A = AffineCryptosystem(AlphabeticStrings())
sage: a, b = (3, 7)
sage: P = A.encoding("Linear"); P
LINEAR
sage: C = A.enciphering(a, b, P)
sage: L = A.brute_force(C)
sage: sorted(L.items())[:26] # display 26 candidate decipherments

((7, 18), SNEPRCIHEDONXEVIKXPCEDCFQONEBREWPPDCFQONEB)]

```

### **deciphering**(*a*, *b*, *C*)

Decrypt the ciphertext *C* with the key (*a*, *b*) using affine cipher decryption.

INPUT:

- *a*, *b* – a secret key belonging to the key space of this affine cipher. This key must be an element of  $\mathbf{Z}/n\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$  such that  $\gcd(a, n) = 1$  with *n* being the size of the ciphertext and plaintext spaces.
- *C* – a string of ciphertext; possibly an empty string. Characters in this string must be encoded using one of the supported alphabets. See the method [encoding\(\)](#) for more information.

OUTPUT:

- The plaintext corresponding to the ciphertext *C*.

EXAMPLES:

Decryption over the capital letters of the English alphabet:

```

sage: A = AffineCryptosystem(AlphabeticStrings())
sage: a, b = (5, 2)
sage: P = A.encoding("Affine functions are linear functions.")
sage: C = A.enciphering(a, b, P); C
CBBQPWBYPMTQUPOCJWFQPWCJBYPMQUPO

```

(continues on next page)

(continued from previous page)

```
sage: P == A.deciphering(a, b, C)
True
```

The previous example can also be worked through using functional notation:

```
sage: A = AffineCryptosystem(AlphabeticStrings())
sage: a, b = (5, 2)
sage: P = A.encoding("Affine functions are linear functions.")
sage: E = A(a, b); E
Affine cipher on Free alphabetic string monoid on A-Z
sage: C = E(P); C
CBBQPWBYPMTQUPOCJWFQPWCJBYPMTQUPO
sage: aInv, bInv = A.inverse_key(a, b)
sage: D = A(aInv, bInv); D
Affine cipher on Free alphabetic string monoid on A-Z
sage: D(C) == P
True
```

If the ciphertext is an empty string, then the plaintext is also an empty string regardless of the value of the secret key:

```
sage: a, b = A.random_key()
sage: A.deciphering(a, b, A.encoding(""))

sage: A.deciphering(a, b, A.encoding(" "))
```

### **enciphering**( $a, b, P$ )

Encrypt the plaintext  $P$  with the key  $(a, b)$  using affine cipher encryption.

INPUT:

- $a, b$  – a secret key belonging to the key space of this affine cipher. This key must be an element of  $\mathbf{Z}/n\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$  such that  $\gcd(a, n) = 1$  with  $n$  being the size of the ciphertext and plaintext spaces.
- $P$  – a string of plaintext; possibly an empty string. Characters in this string must be encoded using one of the supported alphabets. See the method `encoding()` for more information.

OUTPUT:

- The ciphertext corresponding to the plaintext  $P$ .

EXAMPLES:

Encryption over the capital letters of the English alphabet:

```
sage: A = AffineCryptosystem(AlphabeticStrings())
sage: a, b = (3, 6)
sage: P = A.encoding("Affine ciphers work with linear functions.")
sage: A.enciphering(a, b, P)
GVVETSMEZBSFIUWFKUELBNETSGFVOTMLEWTI
```

Now work through the previous example using functional notation:

```
sage: A = AffineCryptosystem(AlphabeticStrings())
sage: a, b = (3, 6)
sage: P = A.encoding("Affine ciphers work with linear functions.")
```

(continues on next page)

(continued from previous page)

```

sage: E = A(a, b); E
Affine cipher on Free alphabetic string monoid on A-Z
sage: E(P)
GVVETSMEZBSFIUWFKUELBNETSGFVOTMLEWTI

```

If the plaintext is an empty string, then the ciphertext is also an empty string regardless of the value of the secret key:

```

sage: a, b = A.random_key()
sage: A.enciphering(a, b, A.encoding(""))
sage: A.enciphering(a, b, A.encoding(" "))

```

### encoding(S)

The encoding of the string  $S$  over the string monoid of this affine cipher. For example, if the string monoid of this cryptosystem is `AlphabeticStringMonoid`, then the encoding of  $S$  would be its upper-case equivalent stripped of all non-alphabetic characters. Only the following alphabet is supported for the affine cipher:

- capital letters of the English alphabet as implemented in `AlphabeticStrings()`

INPUT:

- $S$  – a string, possibly empty.

OUTPUT:

- The encoding of  $S$  over the string monoid of this cryptosystem. If  $S$  is an empty string, return an empty string.

EXAMPLES:

Encoding over the upper-case letters of the English alphabet:

```

sage: A = AffineCryptosystem(AlphabeticStrings())
sage: A.encoding("Affine cipher over capital letters of the English alphabet.")
AFFINECIPHEROVERCAPITALLETTERSOFTHEENGLISHALPHABET

```

The argument  $S$  can be an empty string, in which case an empty string is returned:

```

sage: AffineCryptosystem(AlphabeticStrings()).encoding("")

```

### inverse\_key(a, b)

The inverse key corresponding to the secret key  $(a, b)$ . If  $p$  is a plaintext character so that  $p \in \mathbf{Z}/n\mathbf{Z}$  and  $n$  is the alphabet size, then the ciphertext  $c$  corresponding to  $p$  is

$$c \equiv ap + b \pmod{n}$$

As  $(a, b)$  is a key, then the multiplicative inverse  $a^{-1}$  exists and the original plaintext can be recovered as follows

$$p \equiv a^{-1}(c - b) \pmod{n} \equiv a^{-1}c + a^{-1}(-b) \pmod{n}$$

Therefore the ordered pair  $(a^{-1}, -ba^{-1})$  is the inverse key corresponding to  $(a, b)$ .

INPUT:

- $a, b$  – a secret key for this affine cipher. The ordered pair  $(a, b)$  must be an element of  $\mathbf{Z}/n\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$  such that  $\gcd(a, n) = 1$ .

OUTPUT:

- The inverse key  $(a^{-1}, -ba^{-1})$  corresponding to  $(a, b)$ .

EXAMPLES:

```
sage: A = AffineCryptosystem(AlphabeticStrings())
sage: a, b = (1, 2)
sage: A.inverse_key(a, b)
(1, 24)
sage: A.inverse_key(3, 2)
(9, 8)
```

Suppose that the plaintext and ciphertext spaces are the capital letters of the English alphabet so that  $n = 26$ . If  $\varphi(n)$  is the Euler phi function of  $n$ , then there are  $\varphi(n)$  integers  $0 \leq a < n$  that are relatively prime to  $n$ . For the capital letters of the English alphabet, there are 12 such integers relatively prime to  $n$ :

```
sage: euler_phi(A.alphabet_size())
12
```

And here is a list of those integers:

```
sage: n = A.alphabet_size()
sage: L = [i for i in range(n) if gcd(i, n) == 1]; L
[1, 3, 5, 7, 9, 11, 15, 17, 19, 21, 23, 25]
```

Then a secret key  $(a, b)$  of this shift cryptosystem is such that  $a$  is an element of the list L in the last example. Any inverse key  $(A, B)$  corresponding to  $(a, b)$  is such that  $A$  is also in the list L above:

```
sage: a, b = (3, 9)
sage: a in L
True
sage: aInv, bInv = A.inverse_key(a, b)
sage: aInv, bInv
(9, 23)
sage: aInv in L
True
```

### random\_key()

Generate a random key within the key space of this affine cipher. The generated secret key is an ordered pair  $(a, b) \in \mathbf{Z}/n\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$  with  $n$  being the size of the cipher domain and  $\gcd(a, n) = 1$ . Let  $\varphi(n)$  denote the Euler phi function of  $n$ . Then the affine cipher has  $n \cdot \varphi(n)$  possible keys (see page 10 of [Sti2006]).

OUTPUT:

- A random key within the key space of this affine cryptosystem. The output key is an ordered pair  $(a, b)$ .

EXAMPLES:

```
sage: A = AffineCryptosystem(AlphabeticStrings())
sage: A.random_key() # random
(17, 25)
```

If  $(a, b)$  is a secret key and  $n$  is the size of the plaintext and ciphertext alphabets, then  $\gcd(a, n) = 1$ :

```
sage: a, b = A.random_key()
sage: n = A.alphabet_size()
```

(continues on next page)

(continued from previous page)

```
sage: gcd(a, n)
1
```

**rank\_by\_chi\_square**(*C*, *pdict*)

Use the chi-square statistic to rank all possible keys. Currently, this method only applies to the capital letters of the English alphabet.

## ALGORITHM:

Consider a non-empty alphabet  $A$  consisting of  $n$  elements, and let  $C$  be a ciphertext encoded using elements of  $A$ . The plaintext  $P$  corresponding to  $C$  is also encoded using elements of  $A$ . Let  $M$  be a candidate decipherment of  $C$ , i.e.  $M$  is the result of attempting to decrypt  $C$  using a key  $(a, b)$  which is not necessarily the same key used to encrypt  $P$ . Suppose  $F_A(e)$  is the characteristic frequency probability of  $e \in A$  and let  $F_M(e)$  be the message frequency probability with respect to  $M$ . The characteristic frequency probability distribution of an alphabet is the expected frequency probability distribution for that alphabet. The message frequency probability distribution of  $M$  provides a distribution of the ratio of character occurrences over message length. One can interpret the characteristic frequency probability  $F_A(e)$  as the expected probability, while the message frequency probability  $F_M(e)$  is the observed probability. If  $M$  is of length  $L$ , then the observed frequency of  $e \in A$  is

$$O_M(e) = F_M(e) \cdot L$$

and the expected frequency of  $e \in A$  is

$$E_A(e) = F_A(e) \cdot L$$

The chi-square rank  $R_{\chi^2}(M)$  of  $M$  corresponding to a key  $(a, b) \in \mathbf{Z}/n\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$  is given by

$$R_{\chi^2}(M) = \sum_{e \in A} \frac{(O_M(e) - E_A(e))^2}{E_A(e)}$$

Cryptanalysis by exhaustive key search produces a candidate decipherment  $M_{a,b}$  for each possible key  $(a, b)$ . For a set  $D = \{M_{a_1, b_1}, M_{a_2, b_2}, \dots, M_{a_k, b_k}\}$  of all candidate decipherments corresponding to a ciphertext  $C$ , the smaller is the rank  $R_{\chi^2}(M_{a_i, b_i})$  the more likely that  $(a_i, b_i)$  is the secret key. This key ranking method is based on the Pearson chi-square test [PearsonTest].

## INPUT:

- *C* – The ciphertext, a non-empty string. The ciphertext must be encoded using the upper-case letters of the English alphabet.
- *pdict* – A dictionary of key, possible plaintext pairs. This should be the output of `brute_force()` with `ranking="none"`.

## OUTPUT:

- A list ranking the most likely keys first. Each element of the list is a tuple of key, possible plaintext pairs.

## EXAMPLES:

Use the chi-square statistic to rank all possible keys and their corresponding decipherment:

```
sage: A = AffineCryptosystem(AlphabeticStrings())
sage: a, b = (3, 7)
sage: P = A.encoding("Line.")
sage: C = A.enciphering(a, b, P)
```

(continues on next page)

(continued from previous page)

```

sage: Plist = A.brute_force(C)
sage: Rank = A.rank_by_chi_square(C, Plist)
sage: Rank[:10] # display only the top 10 candidate keys

[((1, 1), NETS),
((3, 7), LINE),
((17, 20), STAD),
((5, 2), SLOT),
((5, 5), HADI),
((9, 25), TSLI),
((17, 15), DELO),
((15, 6), ETUN),
((21, 8), ELID),
((7, 17), HCTE)]

```

As more ciphertext is available, the reliability of the chi-square ranking function increases:

```

sage: A = AffineCryptosystem(AlphabeticStrings())
sage: a, b = (11, 24)
sage: P = A.encoding("Longer message is more information for cryptanalysis.")
sage: C = A.enciphering(a, b, P)
sage: Plist = A.brute_force(C)
sage: Rank = A.rank_by_chi_square(C, Plist)
sage: Rank[:10] # display only the top 10 candidate keys

[((11, 24), LONGERMESSAGIEMOREINFORMATIONFORCRYPTANALYSIS),

((9, 6), BWP SERIEYYCSEGIWREGPLWRICFGWPLWRQRODFCPCBOYGY)]

```

### `rank_by_squared_differences(C, pdict)`

Use the squared-differences measure to rank all possible keys. Currently, this method only applies to the capital letters of the English alphabet.

#### ALGORITHM:

Consider a non-empty alphabet  $A$  consisting of  $n$  elements, and let  $C$  be a ciphertext encoded using elements of  $A$ . The plaintext  $P$  corresponding to  $C$  is also encoded using elements of  $A$ . Let  $M$  be a candidate decipherment of  $C$ , i.e.  $M$  is the result of attempting to decrypt  $C$  using a key  $(a, b)$  which is not necessarily the same key used to encrypt  $P$ . Suppose  $F_A(e)$  is the characteristic frequency probability of  $e \in A$  and let  $F_M(e)$  be the message frequency probability with respect to  $M$ . The characteristic frequency probability distribution of an alphabet is the expected frequency probability distribution for that alphabet. The message frequency probability distribution of  $M$  provides a distribution of the ratio of character occurrences over message length. One can interpret the characteristic frequency probability  $F_A(e)$  as the expected probability, while the message frequency probability  $F_M(e)$  is the observed probability. If  $M$  is of length  $L$ , then the observed frequency of  $e \in A$  is

$$O_M(e) = F_M(e) \cdot L$$

and the expected frequency of  $e \in A$  is

$$E_A(e) = F_A(e) \cdot L$$

The squared-differences, or residual sum of squares, rank  $R_{RSS}(M)$  of  $M$  corresponding to a key  $(a, b) \in \mathbf{Z}/n\mathbf{Z} \times \mathbf{Z}/n\mathbf{Z}$  is given by

$$R_{RSS}(M) = \sum_{e \in A} (O_M(e) - E_A(e))^2$$

Cryptanalysis by exhaustive key search produces a candidate decipherment  $M_{a,b}$  for each possible key  $(a, b)$ . For a set  $D = \{M_{a_1, b_1}, M_{a_2, b_2}, \dots, M_{a_k, b_k}\}$  of all candidate decipherments corresponding to a ciphertext  $C$ , the smaller is the rank  $R_{RSS}(M_{a_i, b_i})$  the more likely that  $(a_i, b_i)$  is the secret key. This key ranking method is based on the residual sum of squares measure [RSS].

INPUT:

- `C` – The ciphertext, a non-empty string. The ciphertext must be encoded using the upper-case letters of the English alphabet.
- `pdict` – A dictionary of key, possible plaintext pairs. This should be the output of `brute_force()` with `ranking="none"`.

OUTPUT:

- A list ranking the most likely keys first. Each element of the list is a tuple of key, possible plaintext pairs.

EXAMPLES:

Use the method of squared differences to rank all possible keys and their corresponding decipherment:

```
sage: A = AffineCryptosystem(AlphabeticStrings())
sage: a, b = (3, 7)
sage: P = A.encoding("Line.")
sage: C = A.enciphering(a, b, P)
sage: Plist = A.brute_force(C)
sage: Rank = A.rank_by_squared_differences(C, Plist)
sage: Rank[:10] # display only the top 10 candidate keys

[[((1, 1), NETS),
((15, 6), ETUN),
((7, 17), HCTE),
((3, 7), LINE),
((17, 15), DELO),
((9, 4), EDWT),
((9, 9), POHE),
((21, 8), ELID),
((17, 20), STAD),
((7, 18), SNEP)]
```

As more ciphertext is available, the reliability of the squared-differences ranking function increases:

```
sage: A = AffineCryptosystem(AlphabeticStrings())
sage: a, b = (11, 24)
sage: P = A.encoding("Longer message is more information for cryptanalysis.")
sage: C = A.enciphering(a, b, P)
sage: Plist = A.brute_force(C)
```

(continues on next page)

(continued from previous page)

```

sage: Rank = A.rank_by_squared_differences(C, Plist)
sage: Rank[:10] # display only the top 10 candidate keys

**class** sage.crypto.classical.HillCryptosystem(*S*, *m*)

Bases: *SymmetricKeyCryptosystem*

Create a Hill cryptosystem defined by the  $m \times m$  matrix space over  $\mathbf{Z}/N\mathbf{Z}$ , where  $N$  is the alphabet size of the string monoid  $S$ .

INPUT:

- $S$  - a string monoid over some alphabet
- $m$  - integer  $> 0$ ; the block length of matrices that specify block permutations

OUTPUT:

- A Hill cryptosystem of block length  $m$  over the alphabet  $S$ .

EXAMPLES:

```

sage: S = AlphabeticStrings()
sage: E = HillCryptosystem(S,3)
sage: E
Hill cryptosystem on Free alphabetic string monoid on A-Z of block length 3
sage: R = IntegerModRing(26)
sage: M = MatrixSpace(R,3,3)
sage: A = M([[1,0,1],[0,1,1],[2,2,3]])
sage: A
[1 0 1]
[0 1 1]
[2 2 3]
sage: e = E(A)
sage: e
Hill cipher on Free alphabetic string monoid on A-Z of block length 3
sage: e(S("LAMAISONBLANCHE"))
JYVKSQPELAYKPV

```

**block\_length()**

The row or column dimension of a matrix specifying a block permutation. Encryption and decryption keys of a Hill cipher are square matrices, i.e. the row and column dimensions of an encryption or decryption key are the same. This row/column dimension is referred to as the *block length*.

OUTPUT:

- The block length of an encryption/decryption key.

EXAMPLES:

```
sage: A = AlphabeticStrings()
sage: n = randint(1, A.ngens() - 1)
sage: H = HillCryptosystem(A, n)
sage: H.block_length() == n
True
```

### **deciphering**( $A, C$ )

Decrypt the ciphertext  $C$  using the key  $A$ .

INPUT:

- $A$  - a key within the key space of this Hill cipher
- $C$  - a string (possibly empty) over the string monoid of this Hill cipher

OUTPUT:

- The plaintext corresponding to the ciphertext  $C$ .

EXAMPLES:

```
sage: H = HillCryptosystem(AlphabeticStrings(), 3)
sage: K = H.random_key()
sage: M = H.encoding("Good day, mate! How ya going?")
sage: H.deciphering(K, H.enciphering(K, M)) == M
True
```

### **enciphering**( $A, M$ )

Encrypt the plaintext  $M$  using the key  $A$ .

INPUT:

- $A$  - a key within the key space of this Hill cipher
- $M$  - a string (possibly empty) over the string monoid of this Hill cipher.

OUTPUT:

- The ciphertext corresponding to the plaintext  $M$ .

EXAMPLES:

```
sage: H = HillCryptosystem(AlphabeticStrings(), 3)
sage: K = H.random_key()
sage: M = H.encoding("Good day, mate! How ya going?")
sage: H.deciphering(K, H.enciphering(K, M)) == M
True
```

### **encoding**( $M$ )

The encoding of the string  $M$  over the string monoid of this Hill cipher. For example, if the string monoid of this Hill cipher is `AlphabeticStringMonoid`, then the encoding of  $M$  would be its upper-case equivalent stripped of all non-alphabetic characters.

INPUT:

- $M$  - a string, possibly empty

OUTPUT:

- The encoding of  $M$  over the string monoid of this Hill cipher.

EXAMPLES:

```
sage: M = "The matrix cipher by Lester S. Hill."
sage: A = AlphabeticStrings()
sage: H = HillCryptosystem(A, 7)
sage: H.encoding(M) == A.encoding(M)
True
```

### `inverse_key(A)`

The inverse key corresponding to the key A.

INPUT:

- A - an invertible matrix of the key space of this Hill cipher

OUTPUT:

- The inverse matrix of A.

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = HillCryptosystem(S, 3)
sage: A = E.random_key()
sage: B = E.inverse_key(A)
sage: M = S("LAMAISONBLANCHE")
sage: e = E(A)
sage: c = E(B)
sage: c(e(M))
LAMAISONBLANCHE
```

### `random_key()`

A random key within the key space of this Hill cipher. That is, generate a random  $m \times m$  matrix to be used as a block permutation, where  $m$  is the block length of this Hill cipher. If  $n$  is the size of the cryptosystem alphabet, then there are  $n^{m^2}$  possible keys. However the number of valid keys, i.e. invertible  $m \times m$  square matrices, is smaller than  $n^{m^2}$ .

OUTPUT:

- A random key within the key space of this Hill cipher.

EXAMPLES:

```
sage: A = AlphabeticStrings()
sage: n = 3
sage: H = HillCryptosystem(A, n)
sage: K = H.random_key()
sage: Ki = H.inverse_key(K)
sage: M = "LAMAISONBLANCHE"
sage: e = H(K)
sage: d = H(Ki)
sage: d(e(A(M))) == A(M)
True
```

`class sage.crypto.classical.ShiftCryptosystem(A)`

Bases: *SymmetricKeyCryptosystem*

Create a shift cryptosystem.

Let  $A = \{a_0, a_1, a_2, \dots, a_{n-1}\}$  be a non-empty alphabet consisting of  $n$  unique elements. Define a mapping  $f : A \rightarrow \mathbf{Z}/n\mathbf{Z}$  from the alphabet  $A$  to the set  $\mathbf{Z}/n\mathbf{Z}$  of integers modulo  $n$ , given by  $f(a_i) = i$ . Thus we can identify each element of the alphabet  $A$  with a unique integer  $0 \leq i < n$ . A key of the shift cipher is an integer  $0 \leq k < n$ . Therefore the key space is  $\mathbf{Z}/n\mathbf{Z}$ . Since we assume that  $A$  does not have repeated elements, the mapping  $f : A \rightarrow \mathbf{Z}/n\mathbf{Z}$  is bijective. Encryption works by moving along the alphabet by  $k$  positions, with wrap around. Decryption reverses the process by moving backwards by  $k$  positions, with wrap around. More generally, let  $k$  be a secret key, i.e. an element of the key space, and let  $p$  be a plaintext character and consequently  $p \in \mathbf{Z}/n\mathbf{Z}$ . Then the ciphertext character  $c$  corresponding to  $p$  is given by

$$c \equiv p + k \pmod{n}$$

Similarly, given a ciphertext character  $c \in \mathbf{Z}/n\mathbf{Z}$  and a secret key  $k$ , we can recover the corresponding plaintext character as follows:

$$p \equiv c - k \pmod{n}$$

Use the bijection  $f : A \rightarrow \mathbf{Z}/n\mathbf{Z}$  to convert  $c$  and  $p$  back to elements of the alphabet  $A$ . Currently, the following alphabets are supported for the shift cipher:

- capital letters of the English alphabet as implemented in `AlphabeticStrings()`
- the alphabet consisting of the hexadecimal number system as implemented in `HexadecimalStrings()`
- the alphabet consisting of the binary number system as implemented in `BinaryStrings()`

#### EXAMPLES:

Some examples illustrating encryption and decryption over various alphabets. Here is an example over the upper-case letters of the English alphabet:

```
sage: S = ShiftCryptosystem(AlphabeticStrings()); S
Shift cryptosystem on Free alphabetic string monoid on A-Z
sage: P = S.encoding("The shift cryptosystem generalizes the Caesar cipher.")
sage: P
THESHIFTCRYPTOSYSTEMGENERALIZESTHECAESARCIPHER
sage: K = 7
sage: C = S.encrypting(K, P); C
AOLZOPMAJYFWAVZFZALTNLULYHSPGLZAOLJHLZHYJPWOLY
sage: S.decrypting(K, C)
THESHIFTCRYPTOSYSTEMGENERALIZESTHECAESARCIPHER
sage: S.decrypting(K, C) == P
True
```

The previous example can also be done as follows:

```
sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: P = S.encoding("The shift cryptosystem generalizes the Caesar cipher.")
sage: K = 7
sage: E = S(K); E
Shift cipher on Free alphabetic string monoid on A-Z
sage: C = E(P); C
AOLZOPMAJYFWAVZFZALTNLULYHSPGLZAOLJHLZHYJPWOLY
sage: D = S(S.inverse_key(K)); D
Shift cipher on Free alphabetic string monoid on A-Z
sage: D(C) == P
True
sage: D(C) == P == D(E(P))
True
```

Over the hexadecimal number system:

```
sage: S = ShiftCryptosystem(HexadecimalStrings()); S
Shift cryptosystem on Free hexadecimal string monoid
sage: P = S.encoding("Encryption & decryption shifts along the alphabet."); P
456e6372797074696f6e20262064656372797074696f6e2073686966747320616c6f6e672074686520616c706861626574
sage: K = 5
sage: C = S.enciphering(K, P); C
9ab3b8c7cec5c9beb4b3757b75b9bab8c7cec5c9beb4b375c8bdbbebbc9c875b6b1b4b3bc75c9bdba75b6b1c5bdb6b7bac9
sage: S.deciphering(K, C)
456e6372797074696f6e20262064656372797074696f6e2073686966747320616c6f6e672074686520616c706861626574
sage: S.deciphering(K, C) == P
True
```

And over the binary number system:

```
sage: S = ShiftCryptosystem(BinaryStrings()); S
Shift cryptosystem on Free binary string monoid
sage: P = S.encoding("The binary alphabet is very insecure."); P
01010100011010000110010100100000011000100110100101101110011000010111001001111001001000000110000101
sage: K = 1
sage: C = S.enciphering(K, P); C
1010101110010111100110101101111100111011001011010010001100111101000110110000110110111110011110100
sage: S.deciphering(K, C)
01010100011010000110010100100000011000100110100101101110011000010111001001111001001000000110000101
sage: S.deciphering(K, C) == P
True
```

A shift cryptosystem with key  $k = 3$  is commonly referred to as the Caesar cipher. Create a Caesar cipher over the upper-case letters of the English alphabet:

```
sage: caesar = ShiftCryptosystem(AlphabeticStrings())
sage: K = 3
sage: P = caesar.encoding("abcdef"); P
ABCDEF
sage: C = caesar.enciphering(K, P); C
DEFGHI
sage: caesar.deciphering(K, C) == P
True
```

Generate a random key for encryption and decryption:

```
sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: P = S.encoding("Shift cipher with a random key.")
sage: K = S.random_key()
sage: C = S.enciphering(K, P)
sage: S.deciphering(K, C) == P
True
```

Decrypting with the key K is equivalent to encrypting with its corresponding inverse key:

```
sage: S.enciphering(S.inverse_key(K), C) == P
True
```

`brute_force(C, ranking='none')`

Attempt a brute force cryptanalysis of the ciphertext C.

INPUT:

- C – A ciphertext over one of the supported alphabets of this shift cryptosystem. See the class *ShiftCryptosystem* for documentation on the supported alphabets.
- ranking – (default "none") the method to use for ranking all possible keys. If ranking="none", then do not use any ranking function. The following ranking functions are supported:
  - "chisquare" – the chi-square ranking function as implemented in the method *rank\_by\_chi\_square()*.
  - "squared\_differences" – the squared differences ranking function as implemented in the method *rank\_by\_squared\_differences()*.

OUTPUT:

- All the possible plaintext sequences corresponding to the ciphertext C. This method effectively uses all the possible keys in this shift cryptosystem to decrypt C. The method is also referred to as exhaustive key search. The output is a dictionary of key, plaintext pairs.

EXAMPLES:

Cryptanalyze using all possible keys for various alphabets. Over the upper-case letters of the English alphabet:

```
sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: P = S.encoding("The shift cryptosystem generalizes the Caesar cipher.")
sage: K = 7
sage: C = S.enciphering(K, P)
sage: Dict = S.brute_force(C)
sage: for k in range(len(Dict)):
.....:     if Dict[k] == P:
.....:         print("key = " + str(k))
key = 7
```

Over the hexadecimal number system:

```
sage: S = ShiftCryptosystem(HexadecimalStrings())
sage: P = S.encoding("Encryption & decryption shifts along the alphabet.")
sage: K = 5
sage: C = S.enciphering(K, P)
sage: Dict = S.brute_force(C)
sage: for k in range(len(Dict)):
.....:     if Dict[k] == P:
.....:         print("key = " + str(k))
key = 5
```

And over the binary number system:

```
sage: S = ShiftCryptosystem(BinaryStrings())
sage: P = S.encoding("The binary alphabet is very insecure.")
sage: K = 1
sage: C = S.enciphering(K, P)
sage: Dict = S.brute_force(C)
sage: for k in range(len(Dict)):
```

(continues on next page)

(continued from previous page)

```
.....:     if Dict[k] == P:
.....:         print("key = " + str(k))
key = 1
```

Don't use any ranking functions, i.e. ranking="none":

```
sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: P = S.encoding("Shifting using modular arithmetic.")
sage: K = 8
sage: C = S.enciphering(K, P)
sage: pdict = S.brute_force(C)
sage: sorted(pdict.items())
```

```

### deciphering( $K, C$ )

Decrypt the ciphertext  $C$  with the key  $K$  using shift cipher decryption.

INPUT:

- $K$  – a secret key; a key belonging to the key space of this shift cipher. This key is an integer  $k$  satisfying the inequality  $0 \leq k < n$ , where  $n$  is the size of the cipher domain.
- $C$  – a string of ciphertext; possibly an empty string. Characters in this string must be encoded using one of the supported alphabets. See the method `encoding()` for more information.

OUTPUT:

- The plaintext corresponding to the ciphertext  $C$ .

EXAMPLES:

Let's perform decryption over the supported alphabets. Here is decryption over the capital letters of the English alphabet:

```
sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: P = S.encoding("Stop shifting me."); P
STOPSHIFTINGME
sage: K = 13
sage: C = S.enciphering(K, P); C
FGBCFUVSGVATZR
sage: S.deciphering(K, C) == P
True
```

Decryption over the hexadecimal number system:

```
sage: S = ShiftCryptosystem(HexadecimalStrings())
sage: P = S.encoding("Shift me now."); P
5368696674206d65206e6f772e
sage: K = 7
sage: C = S.enciphering(K, P); C
cadfd0ddeb97d4dc97d5d6ee95
sage: S.deciphering(K, C) == P
True
```

Decryption over the binary number system:

```
sage: S = ShiftCryptosystem(BinaryStrings())
sage: P = S.encoding("OK, enough shifting."); P
010011110100101100101100001000000110010101101110011011101110101011001110110100000100000011100
sage: K = 1
sage: C = S.enciphering(K, P); C
101100001011010011010011110111110011010100100011001000010001010100110001001011111011111000110
sage: S.deciphering(K, C) == P
True
```

### `enciphering(K, P)`

Encrypt the plaintext  $P$  with the key  $K$  using shift cipher encryption.

INPUT:

- $K$  – a key belonging to the key space of this shift cipher. This key is an integer  $k$  satisfying the inequality  $0 \leq k < n$ , where  $n$  is the size of the cipher domain.
- $P$  – a string of plaintext; possibly an empty string. Characters in this string must be encoded using one of the supported alphabets. See the method `encoding()` for more information.

OUTPUT:

- The ciphertext corresponding to the plaintext P.

EXAMPLES:

Let's perform encryption over the supported alphabets. Here is encryption over the capital letters of the English alphabet:

```
sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: P = S.encoding("Shift your gear."); P
SHIFTYOURGEAR
sage: K = 3
sage: S.enciphering(K, P)
VKLIWBRXUJHDU
```

Encryption over the hexadecimal number system:

```
sage: S = ShiftCryptosystem(HexadecimalStrings())
sage: P = S.encoding("Capitalize with the shift key."); P
4361706974616c697a65207769746820746865207368696674206b65792e
sage: K = 5
sage: S.enciphering(K, P)
98b6c5bec9b6b1becfba75ccb9bd75c9bdba75c8bdbebbc975b0bace73
```

Encryption over the binary number system:

```
sage: S = ShiftCryptosystem(BinaryStrings())
sage: P = S.encoding("Don't shift."); P
010001000110111011011100010011101110100001000000111001101101000011010010110011001110100001011
sage: K = 1
sage: S.enciphering(K, P)
101110111001000010010001110110001000101111011111000110010010111100101101001100110001011110100
```

### encoding(S)

The encoding of the string S over the string monoid of this shift cipher. For example, if the string monoid of this cryptosystem is `AlphabeticStringMonoid`, then the encoding of S would be its upper-case equivalent stripped of all non-alphabetic characters. The following alphabets are supported for the shift cipher:

- capital letters of the English alphabet as implemented in `AlphabeticStrings()`
- the alphabet consisting of the hexadecimal number system as implemented in `HexadecimalStrings()`
- the alphabet consisting of the binary number system as implemented in `BinaryStrings()`

INPUT:

- S – a string, possibly empty.

OUTPUT:

- The encoding of S over the string monoid of this cryptosystem. If S is an empty string, return an empty string.

EXAMPLES:

Encoding over the upper-case letters of the English alphabet:

```
sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: S.encoding("Shift cipher on capital letters of the English alphabet.")
SHIFTCIPHERONCAPITALLETTERSOFTHEENGLISHALPHABET
```

Encoding over the binary system:

```
sage: S = ShiftCryptosystem(BinaryStrings())
sage: S.encoding("Binary")
010000100110100101101110011000010111001001111001
```

Encoding over the hexadecimal system:

```
sage: S = ShiftCryptosystem(HexadecimalStrings())
sage: S.encoding("Over hexadecimal system.")
4f7665722068657861646563696d616c2073797374656d2e
```

The argument S can be an empty string, in which case an empty string is returned:

```
sage: ShiftCryptosystem(AlphabeticStrings()).encoding("")
sage: ShiftCryptosystem(HexadecimalStrings()).encoding("")
sage: ShiftCryptosystem(BinaryStrings()).encoding("")
```

### inverse\_key(K)

The inverse key corresponding to the key K. For the shift cipher, the inverse key corresponding to K is  $-K \bmod n$ , where  $n > 0$  is the size of the cipher domain, i.e. the plaintext/ciphertext space. A key  $k$  of the shift cipher is an integer  $0 \leq k < n$ . The key  $k = 0$  has no effect on either the plaintext or the ciphertext.

INPUT:

- K – a key for this shift cipher. This must be an integer  $k$  such that  $0 \leq k < n$ , where  $n$  is the size of the cipher domain.

OUTPUT:

- The inverse key corresponding to K.

EXAMPLES:

Some random keys and their respective inverse keys:

```
sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: key = S.random_key(); key # random
2
sage: S.inverse_key(key) # random
24
sage: S = ShiftCryptosystem(HexadecimalStrings())
sage: key = S.random_key(); key # random
12
sage: S.inverse_key(key) # random
4
sage: S = ShiftCryptosystem(BinaryStrings())
sage: key = S.random_key(); key # random
1
```

(continues on next page)

(continued from previous page)

```

sage: S.inverse_key(key)      # random
1
sage: key = S.random_key(); key # random
0
sage: S.inverse_key(key)      # random
0

```

Regardless of the value of a key, the addition of the key and its inverse must be equal to the alphabet size. This relationship holds exactly when the value of the key is non-zero:

```

sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: K = S.random_key()
sage: while K == 0:
.....:     K = S.random_key()
sage: invK = S.inverse_key(K)
sage: K + invK == S.alphabet_size()
True
sage: invK + K == S.alphabet_size()
True
sage: K = S.random_key()
sage: while K != 0:
.....:     K = S.random_key()
sage: invK = S.inverse_key(K)
sage: K + invK != S.alphabet_size()
True
sage: K; invK
0
0

```

### random\_key()

Generate a random key within the key space of this shift cipher. The generated key is an integer  $0 \leq k < n$  with  $n$  being the size of the cipher domain. Thus there are  $n$  possible keys in the key space, which is the set  $\mathbf{Z}/n\mathbf{Z}$ . The key  $k = 0$  has no effect on either the plaintext or the ciphertext.

OUTPUT:

- A random key within the key space of this shift cryptosystem.

EXAMPLES:

```

sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: S.random_key() # random
18
sage: S = ShiftCryptosystem(BinaryStrings())
sage: S.random_key() # random
0
sage: S = ShiftCryptosystem(HexadecimalStrings())
sage: S.random_key() # random
5

```

Regardless of the value of a key, the addition of the key and its inverse must be equal to the alphabet size. This relationship holds exactly when the value of the key is non-zero:

```

sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: K = S.random_key()
sage: while K == 0:
.....:     K = S.random_key()
sage: invK = S.inverse_key(K)
sage: K + invK == S.alphabet_size()
True
sage: invK + K == S.alphabet_size()
True
sage: K = S.random_key()
sage: while K != 0:
.....:     K = S.random_key()
sage: invK = S.inverse_key(K)
sage: K + invK != S.alphabet_size()
True
sage: K; invK
0
0

```

### `rank_by_chi_square(C, pdict)`

Use the chi-square statistic to rank all possible keys. Currently, this method only applies to the capital letters of the English alphabet.

ALGORITHM:

Consider a non-empty alphabet  $A$  consisting of  $n$  elements, and let  $C$  be a ciphertext encoded using elements of  $A$ . The plaintext  $P$  corresponding to  $C$  is also encoded using elements of  $A$ . Let  $M$  be a candidate decipherment of  $C$ , i.e.  $M$  is the result of attempting to decrypt  $C$  using a key  $k \in \mathbf{Z}/n\mathbf{Z}$  which is not necessarily the same key used to encrypt  $P$ . Suppose  $F_A(e)$  is the characteristic frequency probability of  $e \in A$  and let  $F_M(e)$  be the message frequency probability with respect to  $M$ . The characteristic frequency probability distribution of an alphabet is the expected frequency probability distribution for that alphabet. The message frequency probability distribution of  $M$  provides a distribution of the ratio of character occurrences over message length. One can interpret the characteristic frequency probability  $F_A(e)$  as the expected probability, while the message frequency probability  $F_M(e)$  is the observed probability. If  $M$  is of length  $L$ , then the observed frequency of  $e \in A$  is

$$O_M(e) = F_M(e) \cdot L$$

and the expected frequency of  $e \in A$  is

$$E_A(e) = F_A(e) \cdot L$$

The chi-square rank  $R_{\chi^2}(M)$  of  $M$  corresponding to a key  $k \in \mathbf{Z}/n\mathbf{Z}$  is given by

$$R_{\chi^2}(M) = \sum_{e \in A} \frac{(O_M(e) - E_A(e))^2}{E_A(e)}$$

Cryptanalysis by exhaustive key search produces a candidate decipherment  $M_k$  for each possible key  $k \in \mathbf{Z}/n\mathbf{Z}$ . For a set  $D = \{M_{k_1}, M_{k_2}, \dots, M_{k_r}\}$  of all candidate decipherments corresponding to a ciphertext  $C$ , the smaller is the rank  $R_{\chi^2}(M_{k_i})$  the more likely that  $k_i$  is the secret key. This key ranking method is based on the Pearson chi-square test [PearsonTest].

INPUT:

- $C$  – The ciphertext, a non-empty string. The ciphertext must be encoded using the upper-case letters of the English alphabet.

- `pdict` – A dictionary of key, possible plaintext pairs. This should be the output of `brute_force()` with `ranking="none"`.

OUTPUT:

- A list ranking the most likely keys first. Each element of the list is a tuple of key, possible plaintext pairs.

EXAMPLES:

Use the chi-square statistic to rank all possible keys and their corresponding decipherment:

```
sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: P = S.encoding("Shi."); P
SHI
sage: K = 5
sage: C = S.enciphering(K, P)
sage: Pdict = S.brute_force(C)
sage: S.rank_by_chi_square(C, Pdict)
```

```
[(9, ODE),

**rank\_by\_squared\_differences**( $C, pdict$ )

Use the squared-differences measure to rank all possible keys. Currently, this method only applies to the capital letters of the English alphabet.

**ALGORITHM:**

Consider a non-empty alphabet  $A$  consisting of  $n$  elements, and let  $C$  be a ciphertext encoded using elements of  $A$ . The plaintext  $P$  corresponding to  $C$  is also encoded using elements of  $A$ . Let  $M$  be a candidate decipherment of  $C$ , i.e.  $M$  is the result of attempting to decrypt  $C$  using a key  $k \in \mathbf{Z}/n\mathbf{Z}$  which is not necessarily the same key used to encrypt  $P$ . Suppose  $F_A(e)$  is the characteristic frequency probability of  $e \in A$  and let  $F_M(e)$  be the message frequency probability with respect to  $M$ . The characteristic frequency probability distribution of an alphabet is the expected frequency probability distribution for that alphabet. The message frequency probability distribution of  $M$  provides a distribution of the ratio of character occurrences over message length. One can interpret the characteristic frequency probability  $F_A(e)$  as the expected probability, while the message frequency probability  $F_M(e)$  is the observed probability. If  $M$  is of length  $L$ , then the observed frequency of  $e \in A$  is

$$O_M(e) = F_M(e) \cdot L$$

and the expected frequency of  $e \in A$  is

$$E_A(e) = F_A(e) \cdot L$$

The squared-differences, or residual sum of squares, rank  $R_{RSS}(M)$  of  $M$  corresponding to a key  $k \in \mathbf{Z}/n\mathbf{Z}$  is given by

$$R_{RSS}(M) = \sum_{e \in A} (O_M(e) - E_A(e))^2$$

Cryptanalysis by exhaustive key search produces a candidate decipherment  $M_k$  for each possible key  $k \in \mathbf{Z}/n\mathbf{Z}$ . For a set  $D = \{M_{k_1}, M_{k_2}, \dots, M_{k_r}\}$  of all candidate decipherments corresponding to a ciphertext  $C$ , the smaller is the rank  $R_{RSS}(M_{k_i})$  the more likely that  $k_i$  is the secret key. This key ranking method is based on the residual sum of squares measure [RSS].

INPUT:

- $C$  – The ciphertext, a non-empty string. The ciphertext must be encoded using the upper-case letters of the English alphabet.
- $\text{pdict}$  – A dictionary of key, possible plaintext pairs. This should be the output of `brute_force()` with `ranking="none"`.

OUTPUT:

- A list ranking the most likely keys first. Each element of the list is a tuple of key, possible plaintext pairs.

EXAMPLES:

Use the method of squared differences to rank all possible keys and their corresponding decipherment:

```
sage: S = ShiftCryptosystem(AlphabeticStrings())
sage: P = S.encoding("Shi."); P
SHI
sage: K = 5
sage: C = S.enciphering(K, P)
sage: Pdict = S.brute_force(C)
sage: S.rank_by_squared_differences(C, Pdict)

```

**class** sage.crypto.classical.SubstitutionCryptosystem(S)

Bases: *SymmetricKeyCryptosystem*

Create a substitution cryptosystem.

INPUT:

- S - a string monoid over some alphabet

OUTPUT:

- A substitution cryptosystem over the alphabet S.

EXAMPLES:

```

sage: M = AlphabeticStrings()
sage: E = SubstitutionCryptosystem(M)
sage: E
Substitution cryptosystem on Free alphabetic string monoid on A-Z
sage: K = M([ 25-i for i in range(26) ])
sage: K
ZYXWVUTSRQPONMLKJIHGFEDCBA
sage: e = E(K)

```

(continues on next page)

(continued from previous page)

```
sage: m = M("THECATINTHEHAT")
sage: e(m)
GSVXZGRMGSVSZG
```

**deciphering**( $K, C$ )

Decrypt the ciphertext  $C$  using the key  $K$ .

INPUT:

- $K$  - a key belonging to the key space of this substitution cipher
- $C$  - a string (possibly empty) over the string monoid of this cryptosystem.

OUTPUT:

- The plaintext corresponding to the ciphertext  $C$ .

EXAMPLES:

```
sage: S = SubstitutionCryptosystem(AlphabeticStrings())
sage: K = S.random_key()
sage: M = S.encoding("Don't substitute me!")
sage: S.deciphering(K, S.enciphering(K, M)) == M
True
```

**enciphering**( $K, M$ )

Encrypt the plaintext  $M$  using the key  $K$ .

INPUT:

- $K$  - a key belonging to the key space of this substitution cipher
- $M$  - a string (possibly empty) over the string monoid of this cryptosystem.

OUTPUT:

- The ciphertext corresponding to the plaintext  $M$ .

EXAMPLES:

```
sage: S = SubstitutionCryptosystem(AlphabeticStrings())
sage: K = S.random_key()
sage: M = S.encoding("Don't substitute me.")
sage: S.deciphering(K, S.enciphering(K, M)) == M
True
```

**encoding**( $M$ )

The encoding of the string  $M$  over the string monoid of this substitution cipher. For example, if the string monoid of this cryptosystem is `AlphabeticStringMonoid`, then the encoding of  $M$  would be its upper-case equivalent stripped of all non-alphabetic characters.

INPUT:

- $M$  - a string, possibly empty

OUTPUT:

- The encoding of  $M$  over the string monoid of this cryptosystem.

EXAMPLES:

```

sage: M = "Peter Pan(ning) for gold."
sage: A = AlphabeticStrings()
sage: S = SubstitutionCryptosystem(A)
sage: S.encoding(M) == A.encoding(M)
True

```

**inverse\_key(K)**

The inverse key corresponding to the key K. The specified key is a permutation of the cryptosystem alphabet.

INPUT:

- K - a key belonging to the key space of this cryptosystem

OUTPUT:

- The inverse key of K.

EXAMPLES:

```

sage: S = AlphabeticStrings()
sage: E = SubstitutionCryptosystem(S)
sage: K = E.random_key()
sage: L = E.inverse_key(K)
sage: M = S("THECATINTHEHAT")
sage: e = E(K)
sage: c = E(L)
sage: c(e(M))
THECATINTHEHAT

```

**random\_key()**

Generate a random key within the key space of this substitution cipher. The generated key is a permutation of the cryptosystem alphabet. Let  $n$  be the length of the alphabet. Then there are  $n!$  possible keys in the key space.

OUTPUT:

- A random key within the key space of this cryptosystem.

EXAMPLES:

```

sage: A = AlphabeticStrings()
sage: S = SubstitutionCryptosystem(A)
sage: K = S.random_key()
sage: Ki = S.inverse_key(K)
sage: M = "THECATINTHEHAT"
sage: e = S(K)
sage: d = S(Ki)
sage: d(e(A(M))) == A(M)
True

```

**class** sage.crypto.classical.**TranspositionCryptosystem**(S, n)

Bases: *SymmetricKeyCryptosystem*

Create a transposition cryptosystem of block length n.

INPUT:

- S - a string monoid over some alphabet

- $n$  - integer  $> 0$ ; a block length of a block permutation

OUTPUT:

- A transposition cryptosystem of block length  $n$  over the alphabet  $S$ .

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = TranspositionCryptosystem(S,14)
sage: E
Transposition cryptosystem on Free alphabetic string monoid on A-Z of block length_
↪14
sage: K = [ 14-i for i in range(14) ]
sage: K
[14, 13, 12, 11, 10, 9, 8, 7, 6, 5, 4, 3, 2, 1]
sage: e = E(K)
sage: e(S("THECATINTHEHAT"))
TAHEHTNITACEHT
```

#### **deciphering**( $K, C$ )

Decrypt the ciphertext  $C$  using the key  $K$ .

INPUT:

- $K$  - a key belonging to the key space of this transposition cipher
- $C$  - a string (possibly empty) over the string monoid of this cryptosystem.

OUTPUT:

- The plaintext corresponding to the ciphertext  $C$ .

EXAMPLES:

```
sage: T = TranspositionCryptosystem(AlphabeticStrings(), 14)
sage: K = T.random_key()
sage: M = T.encoding("The cat in the hat.")
sage: T.deciphering(K, T.enciphering(K, M)) == M
True
```

#### **enciphering**( $K, M$ )

Encrypt the plaintext  $M$  using the key  $K$ .

INPUT:

- $K$  - a key belonging to the key space of this transposition cipher
- $M$  - a string (possibly empty) over the string monoid of this cryptosystem

OUTPUT:

- The ciphertext corresponding to the plaintext  $M$ .

EXAMPLES:

```
sage: T = TranspositionCryptosystem(AlphabeticStrings(), 14)
sage: K = T.random_key()
sage: M = T.encoding("The cat in the hat.")
sage: T.deciphering(K, T.enciphering(K, M)) == M
True
```

**encoding(*M*)**

The encoding of the string *M* over the string monoid of this transposition cipher. For example, if the string monoid of this cryptosystem is `AlphabeticStringMonoid`, then the encoding of *M* would be its upper-case equivalent stripped of all non-alphabetic characters.

INPUT:

- *M* - a string, possibly empty

OUTPUT:

- The encoding of *M* over the string monoid of this cryptosystem.

EXAMPLES:

```
sage: M = "Transposition cipher is not about matrix transpose."
sage: A = AlphabeticStrings()
sage: T = TranspositionCryptosystem(A, 11)
sage: T.encoding(M) == A.encoding(M)
True
```

**inverse\_key(*K*, *check=True*)**

The inverse key corresponding to the key *K*.

INPUT:

- *K* - a key belonging to the key space of this transposition cipher
- *check* - bool (default: True); check that *K* belongs to the key space of this cryptosystem.

OUTPUT:

- The inverse key corresponding to *K*.

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = TranspositionCryptosystem(S, 14)
sage: K = E.random_key()
sage: Ki = E.inverse_key(K)
sage: e = E(K)
sage: d = E(Ki)
sage: M = "THECATINTHEHAT"
sage: C = e(S(M))
sage: d(S(C)) == S(M)
True
```

**random\_key()**

Generate a random key within the key space of this transposition cryptosystem. Let  $n > 0$  be the block length of this cryptosystem. Then there are  $n!$  possible keys.

OUTPUT:

- A random key within the key space of this cryptosystem.

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = TranspositionCryptosystem(S, 14)
sage: K = E.random_key()
```

(continues on next page)

(continued from previous page)

```

sage: Ki = E.inverse_key(K)
sage: e = E(K)
sage: d = E(Ki)
sage: M = "THECATINTHEHAT"
sage: C = e(S(M))
sage: d(S(C)) == S(M)
True

```

**class** sage.crypto.classical.VigenereCryptosystem(*S*, *n*)

Bases: *SymmetricKeyCryptosystem*

Create a Vigenere cryptosystem of block length *n*.

INPUT:

- *S* – a string monoid over some alphabet
- *n* – integer > 0; block length of an encryption/decryption key

OUTPUT:

- A Vigenere cryptosystem of block length *n* over the alphabet *S*.

EXAMPLES:

```

sage: S = AlphabeticStrings()
sage: E = VigenereCryptosystem(S, 14)
sage: E
Vigenere cryptosystem on Free alphabetic string monoid on A-Z of period 14
sage: K = S('ABCDEFGHIJKLMNOP')
sage: K
ABCDEFGHIJKLMNOP
sage: e = E(K)
sage: e
Cipher on Free alphabetic string monoid on A-Z
sage: e(S("THECATINTHEHAT"))
TIGFEYOUBQOSMG

```

**deciphering**(*K*, *C*)

Decrypt the ciphertext *C* using the key *K*.

INPUT:

- *K* – a key belonging to the key space of this Vigenere cipher
- *C* – a string (possibly empty) over the string monoid of this cryptosystem

OUTPUT:

- The plaintext corresponding to the ciphertext *C*.

EXAMPLES:

```

sage: V = VigenereCryptosystem(AlphabeticStrings(), 24)
sage: K = V.random_key()
sage: M = V.encoding("Jack and Jill went up the hill.")
sage: V.deciphering(K, V.encrypting(K, M)) == M
True

```

**enciphering**( $K, M$ )

Encrypt the plaintext  $M$  using the key  $K$ .

INPUT:

- $K$  - a key belonging to the key space of this Vigenere cipher
- $M$  - a string (possibly empty) over the string monoid of this cryptosystem

OUTPUT:

- The ciphertext corresponding to the plaintext  $M$ .

EXAMPLES:

```
sage: V = VigenereCryptosystem(AlphabeticStrings(), 24)
sage: K = V.random_key()
sage: M = V.encoding("Jack and Jill went up the hill.")
sage: V.deciphering(K, V.enciphering(K, M)) == M
True
```

**encoding**( $M$ )

The encoding of the string  $M$  over the string monoid of this Vigenere cipher. For example, if the string monoid of this cryptosystem is `AlphabeticStringMonoid`, then the encoding of  $M$  would be its upper-case equivalent stripped of all non-alphabetic characters.

INPUT:

- $M$  - a string, possibly empty

OUTPUT:

- The encoding of  $M$  over the string monoid of this cryptosystem.

EXAMPLES:

```
sage: A = AlphabeticStrings()
sage: V = VigenereCryptosystem(A, 24)
sage: M = "Jack and Jill went up the hill."
sage: V.encoding(M) == A.encoding(M)
True
```

**inverse\_key**( $K$ )

The inverse key corresponding to the key  $K$ .

INPUT:

- $K$  - a key within the key space of this Vigenere cryptosystem

OUTPUT:

- The inverse key corresponding to  $K$ .

EXAMPLES:

```
sage: S = AlphabeticStrings()
sage: E = VigenereCryptosystem(S, 14)
sage: K = E.random_key()
sage: L = E.inverse_key(K)
sage: M = S("THECATINTHEHAT")
sage: e = E(K)
```

(continues on next page)

(continued from previous page)

```
sage: c = E(L)
sage: c(e(M))
THECATINTHEHAT
```

**random\_key()**

Generate a random key within the key space of this Vigenere cryptosystem. Let  $n > 0$  be the length of the cryptosystem alphabet and let  $m > 0$  be the block length of this cryptosystem. Then there are  $n^m$  possible keys.

OUTPUT:

- A random key within the key space of this cryptosystem.

EXAMPLES:

```
sage: A = AlphabeticStrings()
sage: V = VigenereCryptosystem(A, 14)
sage: M = "THECATINTHEHAT"
sage: K = V.random_key()
sage: Ki = V.inverse_key(K)
sage: e = V(K)
sage: d = V(Ki)
sage: d(e(A(M))) == A(M)
True
```

## CLASSICAL CIPHERS

**class** sage.crypto.classical\_cipher.**AffineCipher**(parent, key)

Bases: *SymmetricKeyCipher*

Affine cipher class. This is the class that does the actual work of encryption and decryption. Users should not directly instantiate or create objects of this class. Instead, functionalities of this class should be accessed via *AffineCryptosystem* as the latter provides a convenient user interface.

**class** sage.crypto.classical\_cipher.**HillCipher**(parent, key)

Bases: *SymmetricKeyCipher*

Hill cipher class

**inverse**()

**class** sage.crypto.classical\_cipher.**ShiftCipher**(parent, key)

Bases: *SymmetricKeyCipher*

Shift cipher class. This is the class that does the actual work of encryption and decryption. Users should not directly instantiate or create objects of this class. Instead, functionalities of this class should be accessed via *ShiftCryptosystem* as the latter provides a convenient user interface.

**class** sage.crypto.classical\_cipher.**SubstitutionCipher**(parent, key)

Bases: *SymmetricKeyCipher*

Substitution cipher class

**inverse**()

**class** sage.crypto.classical\_cipher.**TranspositionCipher**(parent, key)

Bases: *SymmetricKeyCipher*

Transition cipher class

**inverse**()

**class** sage.crypto.classical\_cipher.**VigenereCipher**(parent, key)

Bases: *SymmetricKeyCipher*

Vigenere cipher class

**inverse**()

## SIMPLIFIED DES

A simplified variant of the Data Encryption Standard (DES). Note that Simplified DES or S-DES is for educational purposes only. It is a small-scale version of the DES designed to help beginners understand the basic structure of DES.

AUTHORS:

- Minh Van Nguyen (2009-06): initial version

**class** sage.crypto.block\_cipher.sdes.SimplifiedDES

Bases: SageObject

This class implements the Simplified Data Encryption Standard (S-DES) described in [Sch1996]. Schaefer's S-DES is for educational purposes only and is not secure for practical purposes. S-DES is a version of the DES with all parameters significantly reduced, but at the same time preserving the structure of DES. The goal of S-DES is to allow a beginner to understand the structure of DES, thus laying a foundation for a thorough study of DES. Its goal is as a teaching tool in the same spirit as Phan's *Mini-AES* [Pha2002].

EXAMPLES:

Encrypt a random block of 8-bit plaintext using a random key, decrypt the ciphertext, and compare the result with the original plaintext:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES(); sdes
Simplified DES block cipher with 10-bit keys
sage: bin = BinaryStrings()
sage: P = [bin(str(randint(0, 1)))] for i in range(8)]
sage: K = sdes.random_key()
sage: C = sdes.encrypt(P, K)
sage: plaintext = sdes.decrypt(C, K)
sage: plaintext == P
True
```

We can also encrypt binary strings that are larger than 8 bits in length. However, the number of bits in that binary string must be positive and a multiple of 8:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: bin = BinaryStrings()
sage: P = bin.encoding("Encrypt this using S-DES!")
sage: Mod(len(P), 8) == 0
True
sage: K = sdes.list_to_string(sdes.random_key())
sage: C = sdes(P, K, algorithm="encrypt")
```

(continues on next page)

(continued from previous page)

```
sage: plaintext = sdes(C, K, algorithm="decrypt")
sage: plaintext == P
True
```

**block\_length()**

Return the block length of Schaefer's S-DES block cipher. A key in Schaefer's S-DES is a block of 10 bits.

OUTPUT:

- The block (or key) length in number of bits.

EXAMPLES:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: sdes.block_length()
10
```

**decrypt(C, K)**

Return an 8-bit plaintext corresponding to the ciphertext C, using S-DES decryption with key K. The decryption process of S-DES is as follows. Let  $P$  be the initial permutation function,  $P^{-1}$  the corresponding inverse permutation,  $\Pi_F$  the permutation/substitution function, and  $\sigma$  the switch function. The ciphertext block C first goes through  $P$ , the output of which goes through  $\Pi_F$  using the second subkey. Then we apply the switch function to the output of the last function, and the result is then fed into  $\Pi_F$  using the first subkey. Finally, run the output through  $P^{-1}$  to get the plaintext.

INPUT:

- C – an 8-bit ciphertext; a block of 8 bits
- K – a 10-bit key; a block of 10 bits

OUTPUT:

The 8-bit plaintext corresponding to C, obtained using the key K.

EXAMPLES:

Decrypt an 8-bit ciphertext block:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: C = [0, 1, 0, 1, 0, 1, 0, 1]
sage: K = [1, 0, 1, 0, 0, 0, 0, 0, 1, 0]
sage: sdes.decrypt(C, K)
[0, 0, 0, 1, 0, 1, 0, 1]
```

We can also work with strings of bits:

```
sage: C = "01010101"
sage: K = "1010000010"
sage: sdes.decrypt(sdes.string_to_list(C), sdes.string_to_list(K))
[0, 0, 0, 1, 0, 1, 0, 1]
```

**encrypt(P, K)**

Return an 8-bit ciphertext corresponding to the plaintext P, using S-DES encryption with key K. The encryption process of S-DES is as follows. Let  $P$  be the initial permutation function,  $P^{-1}$  the corresponding inverse permutation,  $\Pi_F$  the permutation/substitution function, and  $\sigma$  the switch function. The plaintext

block  $P$  first goes through  $P$ , the output of which goes through  $\Pi_F$  using the first subkey. Then we apply the switch function to the output of the last function, and the result is then fed into  $\Pi_F$  using the second subkey. Finally, run the output through  $P^{-1}$  to get the ciphertext.

INPUT:

- $P$  – an 8-bit plaintext; a block of 8 bits
- $K$  – a 10-bit key; a block of 10 bits

OUTPUT:

The 8-bit ciphertext corresponding to  $P$ , obtained using the key  $K$ .

EXAMPLES:

Encrypt an 8-bit plaintext block:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: P = [0, 1, 0, 1, 0, 1, 0, 1]
sage: K = [1, 0, 1, 0, 0, 0, 0, 0, 1, 0]
sage: sdes.encrypt(P, K)
[1, 1, 0, 0, 0, 0, 0, 1]
```

We can also work with strings of bits:

```
sage: P = "01010101"
sage: K = "1010000010"
sage: sdes.encrypt(sdes.string_to_list(P), sdes.string_to_list(K))
[1, 1, 0, 0, 0, 0, 0, 1]
```

**initial\_permutation**( $B$ ,  $inverse=False$ )

Return the initial permutation of  $B$ . Denote the initial permutation function by  $P$  and let  $(b_0, b_1, b_2, \dots, b_7)$  be a vector of 8 bits, where each  $b_i \in \{0, 1\}$ . Then

$$P(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7) = (b_1, b_5, b_2, b_0, b_3, b_7, b_4, b_6)$$

The inverse permutation is  $P^{-1}$ :

$$P^{-1}(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7) = (b_3, b_0, b_2, b_4, b_6, b_1, b_7, b_5)$$

INPUT:

- $B$  – list; a block of 8 bits
- $inverse$  – (default: `False`) if `True` then use the inverse permutation  $P^{-1}$ ; if `False` then use the initial permutation  $P$

OUTPUT:

The initial permutation of  $B$  if  $inverse=False$ , or the inverse permutation of  $B$  if  $inverse=True$ .

EXAMPLES:

The initial permutation of a list of 8 bits:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: B = [1, 0, 1, 1, 0, 1, 0, 0]
sage: P = sdes.initial_permutation(B); P
[0, 1, 1, 1, 1, 0, 0, 0]
```

Recovering the original list of 8 bits from the permutation:

```
sage: Pinv = sdes.initial_permutation(P, inverse=True)
sage: Pinv; B
[1, 0, 1, 1, 0, 1, 0, 0]
[1, 0, 1, 1, 0, 1, 0, 0]
```

We can also work with a string of bits:

```
sage: S = "10110100"
sage: L = sdes.string_to_list(S)
sage: P = sdes.initial_permutation(L); P
[0, 1, 1, 1, 1, 0, 0, 0]
sage: sdes.initial_permutation(sdes.string_to_list("01111000"), inverse=True)
[1, 0, 1, 1, 0, 1, 0, 0]
```

### `left_shift(B, n=1)`

Return a circular left shift of  $B$  by  $n$  positions. Let  $B = (b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9)$  be a vector of 10 bits. Then the left shift operation  $L_n$  is performed on the first 5 bits and the last 5 bits of  $B$  separately. That is, if the number of shift positions is  $n=1$ , then  $L_1$  is defined as

$$L_1(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9) = (b_1, b_2, b_3, b_4, b_0, b_6, b_7, b_8, b_9, b_5)$$

If the number of shift positions is  $n=2$ , then  $L_2$  is given by

$$L_2(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9) = (b_2, b_3, b_4, b_0, b_1, b_7, b_8, b_9, b_5, b_6)$$

INPUT:

- $B$  – a list of 10 bits
- $n$  – (default: 1) if  $n=1$  then perform left shift by 1 position; if  $n=2$  then perform left shift by 2 positions. The valid values for  $n$  are 1 and 2, since only up to 2 positions are defined for this circular left shift operation.

OUTPUT:

The circular left shift of each half of  $B$ .

EXAMPLES:

Circular left shift by 1 position of a 10-bit string:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: B = [1, 0, 0, 0, 0, 0, 1, 1, 0, 0]
sage: sdes.left_shift(B)
[0, 0, 0, 0, 1, 1, 1, 0, 0, 0]
sage: sdes.left_shift([1, 0, 1, 0, 0, 0, 0, 0, 1, 0])
[0, 1, 0, 0, 1, 0, 0, 1, 0, 0]
```

Circular left shift by 2 positions of a 10-bit string:

```
sage: B = [0, 0, 0, 0, 1, 1, 1, 0, 0, 0]
sage: sdes.left_shift(B, n=2)
[0, 0, 1, 0, 0, 0, 0, 0, 1, 1]
```

Here we work with a string of bits:

```

sage: S = "1000001100"
sage: L = sdes.string_to_list(S)
sage: sdes.left_shift(L)
[0, 0, 0, 0, 1, 1, 1, 0, 0, 0]
sage: sdes.left_shift(sdes.string_to_list("1010000010"), n=2)
[1, 0, 0, 1, 0, 0, 1, 0, 0, 0]

```

**list\_to\_string(*B*)**

Return a binary string representation of the list *B*.

INPUT:

- *B* – a non-empty list of bits

OUTPUT:

The binary string representation of *B*.

EXAMPLES:

A binary string representation of a list of bits:

```

sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: L = [0, 0, 0, 0, 1, 1, 0, 1, 0, 0]
sage: sdes.list_to_string(L)
0000110100

```

**permutation10(*B*)**

Return a permutation of a 10-bit string. This permutation is called  $P_{10}$  and is specified as follows. Let  $(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9)$  be a vector of 10 bits where each  $b_i \in \{0, 1\}$ . Then  $P_{10}$  is given by

$$P_{10}(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9) = (b_2, b_4, b_1, b_6, b_3, b_9, b_0, b_8, b_7, b_5)$$

INPUT:

- *B* – a block of 10-bit string

OUTPUT:

A permutation of *B*.

EXAMPLES:

Permute a 10-bit string:

```

sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: B = [1, 1, 0, 0, 1, 0, 0, 1, 0, 1]
sage: sdes.permutation10(B)
[0, 1, 1, 0, 0, 1, 1, 0, 1, 0]
sage: sdes.permutation10([0, 1, 1, 0, 1, 0, 0, 1, 0, 1])
[1, 1, 1, 0, 0, 1, 0, 0, 1, 0]
sage: sdes.permutation10([1, 0, 1, 0, 0, 0, 0, 0, 1, 0])
[1, 0, 0, 0, 0, 0, 1, 1, 0, 0]

```

Here we work with a string of bits:

```

sage: S = "1100100101"
sage: L = sdes.string_to_list(S)
sage: sdes.permutation10(L)
[0, 1, 1, 0, 0, 1, 1, 0, 1, 0]
sage: sdes.permutation10(sdes.string_to_list("0110100101"))
[1, 1, 1, 0, 0, 1, 0, 0, 1, 0]

```

**permutation4(B)**

Return a permutation of a 4-bit string. This permutation is called  $P_4$  and is specified as follows. Let  $(b_0, b_1, b_2, b_3)$  be a vector of 4 bits where each  $b_i \in \{0, 1\}$ . Then  $P_4$  is defined by

$$P_4(b_0, b_1, b_2, b_3) = (b_1, b_3, b_2, b_0)$$

INPUT:

- B – a block of 4-bit string

OUTPUT:

A permutation of B.

EXAMPLES:

Permute a 4-bit string:

```

sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: B = [1, 1, 0, 0]
sage: sdes.permutation4(B)
[1, 0, 0, 1]
sage: sdes.permutation4([0, 1, 0, 1])
[1, 1, 0, 0]

```

We can also work with a string of bits:

```

sage: S = "1100"
sage: L = sdes.string_to_list(S)
sage: sdes.permutation4(L)
[1, 0, 0, 1]
sage: sdes.permutation4(sdes.string_to_list("0101"))
[1, 1, 0, 0]

```

**permutation8(B)**

Return a permutation of an 8-bit string. This permutation is called  $P_8$  and is specified as follows. Let  $(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9)$  be a vector of 10 bits where each  $b_i \in \{0, 1\}$ . Then  $P_8$  picks out 8 of those 10 bits and permutes those 8 bits:

$$P_8(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9) = (b_5, b_2, b_6, b_3, b_7, b_4, b_9, b_8)$$

INPUT:

- B – a block of 10-bit string

OUTPUT:

Pick out 8 of the 10 bits of B and permute those 8 bits.

EXAMPLES:

Permute a 10-bit string:

```

sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: B = [1, 1, 0, 0, 1, 0, 0, 1, 0, 1]
sage: sdes.permutation8(B)
[0, 0, 0, 0, 1, 1, 1, 0]
sage: sdes.permutation8([0, 1, 1, 0, 1, 0, 0, 1, 0, 1])
[0, 1, 0, 0, 1, 1, 1, 0]
sage: sdes.permutation8([0, 0, 0, 0, 1, 1, 1, 0, 0, 0])
[1, 0, 1, 0, 0, 1, 0, 0]

```

We can also work with a string of bits:

```

sage: S = "1100100101"
sage: L = sdes.string_to_list(S)
sage: sdes.permutation8(L)
[0, 0, 0, 0, 1, 1, 1, 0]
sage: sdes.permutation8(sdes.string_to_list("0110100101"))
[0, 1, 0, 0, 1, 1, 1, 0]

```

**permute\_substitute**( $B, key$ )

Apply the function  $\Pi_F$  on the block  $B$  using subkey  $key$ . Let  $(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7)$  be a vector of 8 bits where each  $b_i \in \{0, 1\}$ , let  $L$  and  $R$  be the leftmost 4 bits and rightmost 4 bits of  $B$  respectively, and let  $F$  be a function mapping 4-bit strings to 4-bit strings. Then

$$\Pi_F(L, R) = (L \oplus F(R, S), R)$$

where  $S$  is a subkey and  $\oplus$  denotes the bit-wise exclusive-OR function.

The function  $F$  can be described as follows. Its 4-bit input block  $(n_0, n_1, n_2, n_3)$  is first expanded into an 8-bit block to become  $(n_3, n_0, n_1, n_2, n_1, n_2, n_3, n_0)$ . This is usually represented as follows

$$\begin{array}{c|cc|c} n_3 & n_0 & n_1 & n_2 \\ n_1 & n_2 & n_3 & n_0 \end{array}$$

Let  $K = (k_0, k_1, k_2, k_3, k_4, k_5, k_6, k_7)$  be an 8-bit subkey. Then  $K$  is added to the above expanded input block using exclusive-OR to produce

$$\begin{array}{c|cc|cc} n_3 + k_0 & n_0 + k_1 & n_1 + k_2 & n_2 + k_3 & = & p_{0,0} & p_{0,1} & p_{0,2} & p_{0,3} \\ n_1 + k_4 & n_2 + k_5 & n_3 + k_6 & n_0 + k_7 & & p_{1,0} & p_{1,1} & p_{1,2} & p_{1,3} \end{array}$$

Now read the first row as the 4-bit string  $p_{0,0}p_{0,3}p_{0,1}p_{0,2}$  and input this 4-bit string through S-box  $S_0$  to get a 2-bit output.

| Input | Output | Input | Output |
|-------|--------|-------|--------|
| 0000  | 01     | 1000  | 00     |
| 0001  | 00     | 1001  | 10     |
| 0010  | 11     | 1010  | 01     |
| 0011  | 10     | 1011  | 11     |
| 0100  | 11     | 1100  | 11     |
| 0101  | 10     | 1101  | 01     |
| 0110  | 01     | 1110  | 11     |
| 0111  | 00     | 1111  | 10     |

Next read the second row as the 4-bit string  $p_{1,0}p_{1,3}p_{1,1}p_{1,2}$  and input this 4-bit string through S-box  $S_1$  to

get another 2-bit output.

|         | Input | Output | Input | Output |
|---------|-------|--------|-------|--------|
|         | 0000  | 00     | 1000  | 11     |
|         | 0001  | 01     | 1001  | 00     |
|         | 0010  | 10     | 1010  | 01     |
| $S_1 =$ | 0011  | 11     | 1011  | 00     |
|         | 0100  | 10     | 1100  | 10     |
|         | 0101  | 00     | 1101  | 01     |
|         | 0110  | 01     | 1110  | 00     |
|         | 0111  | 11     | 1111  | 11     |

Denote the 4 bits produced by  $S_0$  and  $S_1$  as  $b_0b_1b_2b_3$ . This 4-bit string undergoes another permutation called  $P_4$  as follows:

$$P_4(b_0, b_1, b_2, b_3) = (b_1, b_3, b_2, b_0)$$

The output of  $P_4$  is the output of the function  $F$ .

INPUT:

- B – a list of 8 bits
- key – an 8-bit subkey

OUTPUT:

The result of applying the function  $\Pi_F$  to B.

EXAMPLES:

Applying the function  $\Pi_F$  to an 8-bit block and an 8-bit subkey:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: B = [1, 0, 1, 1, 1, 1, 0, 1]
sage: K = [1, 1, 0, 1, 0, 1, 0, 1]
sage: sdes.permute_substitute(B, K)
[1, 0, 1, 0, 1, 1, 0, 1]
```

We can also work with strings of bits:

```
sage: B = "10111101"
sage: K = "11010101"
sage: B = sdes.string_to_list(B); K = sdes.string_to_list(K)
sage: sdes.permute_substitute(B, K)
[1, 0, 1, 0, 1, 1, 0, 1]
```

### random\_key()

Return a random 10-bit key.

EXAMPLES:

The size of each key is the same as the block size:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: key = sdes.random_key()
sage: len(key) == sdes.block_length()
True
```

**sbox()**

Return the S-boxes of simplified DES.

EXAMPLES:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: sbox = sdes.sbox()
sage: sbox[0]; sbox[1]
(1, 0, 3, 2, 3, 2, 1, 0, 0, 2, 1, 3, 3, 1, 3, 2)
(0, 1, 2, 3, 2, 0, 1, 3, 3, 0, 1, 0, 2, 1, 0, 3)
```

**string\_to\_list(S)**

Return a list representation of the binary string S.

INPUT:

- S – a string of bits

OUTPUT:

A list representation of the string S.

EXAMPLES:

A list representation of a string of bits:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: S = "0101010110"
sage: sdes.string_to_list(S)
[0, 1, 0, 1, 0, 1, 0, 1, 1, 0]
```

**subkey(K, n=1)**

Return the n-th subkey based on the key K.

INPUT:

- K – a 10-bit secret key of this Simplified DES
- n – (default: 1) if n=1 then return the first subkey based on K; if n=2 then return the second subkey. The valid values for n are 1 and 2, since only two subkeys are defined for each secret key in Schaefer's S-DES.

OUTPUT:

The n-th subkey based on the secret key K.

EXAMPLES:

Obtain the first subkey from a secret key:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: key = [1, 0, 1, 0, 0, 0, 0, 0, 1, 0]
sage: sdes.subkey(key, n=1)
[1, 0, 1, 0, 0, 1, 0, 0]
```

Obtain the second subkey from a secret key:

```
sage: key = [1, 0, 1, 0, 0, 0, 0, 1, 0]
sage: sdes.subkey(key, n=2)
[0, 1, 0, 0, 0, 0, 1, 1]
```

We can also work with strings of bits:

```
sage: K = "1010010010"
sage: L = sdes.string_to_list(K)
sage: sdes.subkey(L, n=1)
[1, 0, 1, 0, 0, 1, 0, 1]
sage: sdes.subkey(sdes.string_to_list("0010010011"), n=2)
[0, 1, 1, 0, 1, 0, 1, 0]
```

### switch(B)

Interchange the first 4 bits with the last 4 bits in the list B of 8 bits. Let  $(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7)$  be a vector of 8 bits, where each  $b_i \in \{0, 1\}$ . Then the switch function  $\sigma$  is given by

$$\sigma(b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7) = (b_4, b_5, b_6, b_7, b_0, b_1, b_2, b_3)$$

INPUT:

- B – list; a block of 8 bits

OUTPUT:

A block of the same dimension, but in which the first 4 bits from B has been switched for the last 4 bits in B.

EXAMPLES:

Interchange the first 4 bits with the last 4 bits:

```
sage: from sage.crypto.block_cipher.sdes import SimplifiedDES
sage: sdes = SimplifiedDES()
sage: B = [1, 1, 1, 0, 1, 0, 0, 0]
sage: sdes.switch(B)
[1, 0, 0, 0, 1, 1, 1, 0]
sage: sdes.switch([1, 1, 1, 1, 0, 0, 0, 0])
[0, 0, 0, 0, 1, 1, 1, 1]
```

We can also work with a string of bits:

```
sage: S = "11101000"
sage: L = sdes.string_to_list(S)
sage: sdes.switch(L)
[1, 0, 0, 0, 1, 1, 1, 0]
sage: sdes.switch(sdes.string_to_list("11110000"))
[0, 0, 0, 0, 1, 1, 1, 1]
```

## MINI-AES

A simplified variant of the Advanced Encryption Standard (AES). Note that Mini-AES is for educational purposes only. It is a small-scale version of the AES designed to help beginners understand the basic structure of AES.

AUTHORS:

- Minh Van Nguyen (2009-05): initial version

**class** sage.crypto.block\_cipher.miniaes.MiniaES

Bases: SageObject

This class implements the Mini Advanced Encryption Standard (Mini-AES) described in [Pha2002]. Note that Phan's Mini-AES is for educational purposes only and is not secure for practical purposes. Mini-AES is a version of the AES with all parameters significantly reduced, but at the same time preserving the structure of AES. The goal of Mini-AES is to allow a beginner to understand the structure of AES, thus laying a foundation for a thorough study of AES. Its goal is as a teaching tool and is different from the *SR* small scale variants of the AES. *SR* defines a family of parameterizable variants of the AES suitable as a framework for comparing different cryptanalytic techniques that can be brought to bear on the AES.

EXAMPLES:

Encrypt a plaintext:

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: MS = MatrixSpace(K, 2, 2)
sage: P = MS([K("x^3 + x"), K("x^2 + 1"), K("x^2 + x"), K("x^3 + x^2")]); P

[ x^3 + x  x^2 + 1]
[ x^2 + x x^3 + x^2]
sage: key = MS([K("x^3 + x^2"), K("x^3 + x"), K("x^3 + x^2 + x"), K("x^2 + x + 1
↪")]); key

[ x^3 + x^2  x^3 + x]
[x^3 + x^2 + x  x^2 + x + 1]
sage: C = maes.encrypt(P, key); C
[ x^3 + x^2 + 1 x^3 + x^2 + x + 1]
[ x  x^3 + x^2 + x]
```

Decrypt the result:

```
sage: plaintext = maes.decrypt(C, key)
sage: plaintext; P
```

(continues on next page)

(continued from previous page)

```
[ x^3 + x  x^2 + 1]
[ x^2 + x x^3 + x^2]

[ x^3 + x  x^2 + 1]
[ x^2 + x x^3 + x^2]
sage: plaintext == P
True
```

We can also work directly with binary strings:

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: bin = BinaryStrings()
sage: key = bin.encoding("KE"); key
0100101101000101
sage: P = bin.encoding("Encrypt this secret message!"); P
010001010110111001100011011100100111100101110000011101000010000001110100011010000110100101110011001
sage: C = maes(P, key, algorithm="encrypt"); C
11100000101000010110001101101001110110010010111011010001100111100000101000101111100110010010100001
sage: plaintext = maes(C, key, algorithm="decrypt")
sage: plaintext == P
True
```

Now we work with integers  $n$  such that  $0 \leq n \leq 15$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: P = [n for n in range(16)]; P
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]
sage: key = [2, 3, 11, 0]; key
[2, 3, 11, 0]
sage: P = maes.integer_to_binary(P); P
00000000100100011010001010110011110001001101010111100110111101111
sage: key = maes.integer_to_binary(key); key
0010001110110000
sage: C = maes(P, key, algorithm="encrypt"); C
0011101000101110010011000101010100011101010000111000100100011010
sage: plaintext = maes(C, key, algorithm="decrypt")
sage: plaintext == P
True
```

Generate some random plaintext and a random secret key. Encrypt the plaintext using that secret key and decrypt the result. Then compare the decrypted plaintext with the original plaintext:

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: MS = MatrixSpace(FiniteField(16, "x"), 2, 2)
sage: P = MS.random_element()
sage: key = maes.random_key()
sage: C = maes.encrypt(P, key)
sage: plaintext = maes.decrypt(C, key)
```

(continues on next page)

(continued from previous page)

```
sage: plaintext == P
True
```

**GF\_to\_binary(*G*)**

Return the binary representation of *G*. If *G* is an element of the finite field  $\mathbf{F}_{2^4}$ , then obtain the binary representation of *G*. If *G* is a list of elements belonging to  $\mathbf{F}_{2^4}$ , obtain the 4-bit representation of each element of the list, then concatenate the resulting 4-bit strings into a binary string. If *G* is a matrix with entries over  $\mathbf{F}_{2^4}$ , convert each matrix entry to its 4-bit representation, then concatenate the 4-bit strings. The concatenation is performed starting from the top-left corner of the matrix, working across left to right, top to bottom. Each element of  $\mathbf{F}_{2^4}$  can be associated with a unique 4-bit string according to the following table:

| 4-bit string | $\mathbf{F}_{2^4}$ | 4-bit string | $\mathbf{F}_{2^4}$  |
|--------------|--------------------|--------------|---------------------|
| 0000         | 0                  | 1000         | $x^3$               |
| 0001         | 1                  | 1001         | $x^3 + 1$           |
| 0010         | $x$                | 1010         | $x^3 + x$           |
| 0011         | $x + 1$            | 1011         | $x^3 + x + 1$       |
| 0100         | $x^2$              | 1100         | $x^3 + x^2$         |
| 0101         | $x^2 + 1$          | 1101         | $x^3 + x^2 + 1$     |
| 0110         | $x^2 + x$          | 1110         | $x^3 + x^2 + x$     |
| 0111         | $x^2 + x + 1$      | 1111         | $x^3 + x^2 + x + 1$ |

INPUT:

- *G* – an element of  $\mathbf{F}_{2^4}$ , a list of elements of  $\mathbf{F}_{2^4}$ , or a matrix over  $\mathbf{F}_{2^4}$

OUTPUT:

- A binary string representation of *G*.

EXAMPLES:

Obtain the binary representation of all elements of  $\mathbf{F}_{2^4}$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: S = Set(K); len(S) # GF(2^4) has this many elements
16
sage: [maes.GF_to_binary(S[i]) for i in range(len(S))]

[0000,
0001,
0010,
0011,
0100,
0101,
0110,
0111,
1000,
1001,
1010,
1011,
1100,
1101,
```

(continues on next page)

(continued from previous page)

```
1110,
1111]
```

The binary representation of a list of elements belonging to  $F_{2^4}$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: G = [K("x^2 + x + 1"), K("x^3 + x^2"), K("x"), K("x^3 + x + 1"), K("x^3 +
↪x^2 + x + 1"), K("x^2 + x"), K("1"), K("x^2 + x + 1")]
sage: maes.GF_to_binary(G)
01111100001010111111011000010111
```

The binary representation of a matrix over  $F_{2^4}$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: MS = MatrixSpace(K, 2, 2)
sage: G = MS([K("x^3 + x^2"), K("x + 1"), K("x^2 + x + 1"), K("x^3 + x^2 + x
↪")]); G

[      x^3 + x^2      x + 1]
[ x^2 + x + 1 x^3 + x^2 + x]
sage: maes.GF_to_binary(G)
1100001101111110

sage: MS = MatrixSpace(K, 2, 4)
sage: G = MS([K("x^2 + x + 1"), K("x^3 + x^2"), K("x"), K("x^3 + x + 1"), K("x^
↪3 + x^2 + x + 1"), K("x^2 + x"), K("1"), K("x^2 + x + 1")]); G

[      x^2 + x + 1      x^3 + x^2      x      x^3 + x + 1]
[x^3 + x^2 + x + 1      x^2 + x      1      x^2 + x + 1]
sage: maes.GF_to_binary(G)
01111100001010111111011000010111
```

**GF\_to\_integer(G)**

Return the integer representation of the finite field element G. If G is an element of the finite field  $F_{2^4}$ , then obtain the integer representation of G. If G is a list of elements belonging to  $F_{2^4}$ , obtain the integer representation of each element of the list, and return the result as a list of integers. If G is a matrix with entries over  $F_{2^4}$ , convert each matrix entry to its integer representation, and return the result as a list of integers. The resulting list is obtained by starting from the top-left corner of the matrix, working across left to right, top to bottom. Each element of  $F_{2^4}$  can be associated with a unique integer according to the following table:

| integer | $F_{2^4}$     | integer | $F_{2^4}$           |
|---------|---------------|---------|---------------------|
| 0       | 0             | 8       | $x^3$               |
| 1       | 1             | 9       | $x^3 + 1$           |
| 2       | $x$           | 10      | $x^3 + x$           |
| 3       | $x + 1$       | 11      | $x^3 + x + 1$       |
| 4       | $x^2$         | 12      | $x^3 + x^2$         |
| 5       | $x^2 + 1$     | 13      | $x^3 + x^2 + 1$     |
| 6       | $x^2 + x$     | 14      | $x^3 + x^2 + x$     |
| 7       | $x^2 + x + 1$ | 15      | $x^3 + x^2 + x + 1$ |

INPUT:

- $G$  – an element of  $\mathbb{F}_{2^4}$ , a list of elements belonging to  $\mathbb{F}_{2^4}$ , or a matrix over  $\mathbb{F}_{2^4}$

OUTPUT:

- The integer representation of  $G$ .

EXAMPLES:

Obtain the integer representation of all elements of  $\mathbb{F}_{2^4}$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: S = Set(K); len(S) # GF(2^4) has this many elements
16
sage: [maes.GF_to_integer(S[i]) for i in range(len(S))]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]
```

The integer representation of a list of elements belonging to  $\mathbb{F}_{2^4}$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: G = [K("x^2 + x + 1"), K("x^3 + x^2"), K("x"), K("x^3 + x + 1"), K("x^3 +
↵x^2 + x + 1"), K("x^2 + x"), K("1"), K("x^2 + x + 1")]
sage: maes.GF_to_integer(G)
[7, 12, 2, 11, 15, 6, 1, 7]
```

The integer representation of a matrix over  $\mathbb{F}_{2^4}$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: MS = MatrixSpace(K, 2, 2)
sage: G = MS([K("x^3 + x^2"), K("x + 1"), K("x^2 + x + 1"), K("x^3 + x^2 + x
↵")]); G

[      x^3 + x^2      x + 1]
[ x^2 + x + 1 x^3 + x^2 + x]
sage: maes.GF_to_integer(G)
[12, 3, 7, 14]
sage: MS = MatrixSpace(K, 2, 4)
sage: G = MS([K("x^2 + x + 1"), K("x^3 + x^2"), K("x"), K("x^3 + x + 1"), K("x^
↵3 + x^2 + x + 1"), K("x^2 + x"), K("1"), K("x^2 + x + 1")]); G

[      x^2 + x + 1      x^3 + x^2      x      x^3 + x + 1]
[x^3 + x^2 + x + 1      x^2 + x      1      x^2 + x + 1]
sage: maes.GF_to_integer(G)
[7, 12, 2, 11, 15, 6, 1, 7]
```

**add\_key**(*block*, *rkey*)

Return the matrix addition of *block* and *rkey*. Both *block* and *rkey* are  $2 \times 2$  matrices over the finite field  $\mathbb{F}_{2^4}$ . This method just return the matrix addition of these two matrices.

INPUT:

- `block` – a  $2 \times 2$  matrix with entries over  $\mathbb{F}_{2^4}$
- `rkey` – a round key; a  $2 \times 2$  matrix with entries over  $\mathbb{F}_{2^4}$

OUTPUT:

- The matrix addition of `block` and `rkey`.

EXAMPLES:

We can work with elements of  $\mathbb{F}_{2^4}$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: MS = MatrixSpace(K, 2, 2)
sage: D = MS([ [K("x^3 + x^2 + x + 1"), K("x^3 + x")], [K("0"), K("x^3 + x^2")] ]
↪); D

[x^3 + x^2 + x + 1      x^3 + x]
[                    0      x^3 + x^2]
sage: k = MS([ [K("x^2 + 1"), K("x^3 + x^2 + x + 1")], [K("x + 1"), K("0")] ]);
↪k

[      x^2 + 1  x^3 + x^2 + x + 1]
[      x + 1      0]
sage: maes.add_key(D, k)

[ x^3 + x  x^2 + 1]
[ x + 1  x^3 + x^2]
```

Or work with binary strings:

```
sage: bin = BinaryStrings()
sage: B = bin.encoding("We"); B
0101011101100101
sage: B = MS(maes.binary_to_GF(B)); B

[      x^2 + 1  x^2 + x + 1]
[      x^2 + x      x^2 + 1]
sage: key = bin.encoding("KY"); key
0100101101011001
sage: key = MS(maes.binary_to_GF(key)); key

[      x^2  x^3 + x + 1]
[      x^2 + 1      x^3 + 1]
sage: maes.add_key(B, key)

[      1  x^3 + x^2]
[      x + 1  x^3 + x^2]
```

We can also work with integers  $n$  such that  $0 \leq n \leq 15$ :

```
sage: N = [2, 3, 5, 7]; N
[2, 3, 5, 7]
sage: key = [9, 11, 13, 15]; key
```

(continues on next page)

(continued from previous page)

```
[9, 11, 13, 15]
sage: N = MS(maes.integer_to_GF(N)); N

[      x      x + 1]
[  x^2 + 1 x^2 + x + 1]
sage: key = MS(maes.integer_to_GF(key)); key

[      x^3 + 1      x^3 + x + 1]
[  x^3 + x^2 + 1 x^3 + x^2 + x + 1]
sage: maes.add_key(N, key)

[x^3 + x + 1      x^3]
[      x^3      x^3]
```

**binary\_to\_GF(B)**

Return a list of elements of  $\mathbf{F}_{2^4}$  that represents the binary string B. The number of bits in B must be greater than zero and a multiple of 4. Each nibble (or 4-bit string) is uniquely associated with an element of  $\mathbf{F}_{2^4}$  as specified by the following table:

| 4-bit string | $\mathbf{F}_{2^4}$ | 4-bit string | $\mathbf{F}_{2^4}$  |
|--------------|--------------------|--------------|---------------------|
| 0000         | 0                  | 1000         | $x^3$               |
| 0001         | 1                  | 1001         | $x^3 + 1$           |
| 0010         | $x$                | 1010         | $x^3 + x$           |
| 0011         | $x + 1$            | 1011         | $x^3 + x + 1$       |
| 0100         | $x^2$              | 1100         | $x^3 + x^2$         |
| 0101         | $x^2 + 1$          | 1101         | $x^3 + x^2 + 1$     |
| 0110         | $x^2 + x$          | 1110         | $x^3 + x^2 + x$     |
| 0111         | $x^2 + x + 1$      | 1111         | $x^3 + x^2 + x + 1$ |

INPUT:

- B – a binary string, where the number of bits is positive and a multiple of 4

OUTPUT:

- A list of elements of the finite field  $\mathbf{F}_{2^4}$  that represent the binary string B.

EXAMPLES:

Obtain all the elements of the finite field  $\mathbf{F}_{2^4}$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: bin = BinaryStrings()
sage: B = bin("0000000100100011010001010110011110001001101010111100110111101111")
↪")
sage: maes.binary_to_GF(B)

[0,
1,
x,
x + 1,
x^2,
x^2 + 1,
x^2 + x,
```

(continues on next page)

(continued from previous page)

```
x^2 + x + 1,
x^3,
x^3 + 1,
x^3 + x,
x^3 + x + 1,
x^3 + x^2,
x^3 + x^2 + 1,
x^3 + x^2 + x,
x^3 + x^2 + x + 1]
```

**binary\_to\_integer(B)**

Return a list of integers representing the binary string B. The number of bits in B must be greater than zero and a multiple of 4. Each nibble (or 4-bit string) is uniquely associated with an integer as specified by the following table:

| 4-bit string | integer | 4-bit string | integer |
|--------------|---------|--------------|---------|
| 0000         | 0       | 1000         | 8       |
| 0001         | 1       | 1001         | 9       |
| 0010         | 2       | 1010         | 10      |
| 0011         | 3       | 1011         | 11      |
| 0100         | 4       | 1100         | 12      |
| 0101         | 5       | 1101         | 13      |
| 0110         | 6       | 1110         | 14      |
| 0111         | 7       | 1111         | 15      |

INPUT:

- B – a binary string, where the number of bits is positive and a multiple of 4

OUTPUT:

- A list of integers that represent the binary string B.

EXAMPLES:

Obtain the integer representation of every 4-bit string:

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: bin = BinaryStrings()
sage: B = bin("00000000100100011010001010110011110001001101010111100110111101111")
↪")
sage: maes.binary_to_integer(B)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]
```

**block\_length()**

Return the block length of Phan’s Mini-AES block cipher. A key in Phan’s Mini-AES is a block of 16 bits. Each nibble of a key can be considered as an element of the finite field  $\mathbb{F}_{2^4}$ . Therefore the key consists of four elements from  $\mathbb{F}_{2^4}$ .

OUTPUT:

- The block (or key) length in number of bits.

EXAMPLES:

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: maes.block_length()
16
```

**decrypt**( $C$ ,  $key$ )

Use Phan's Mini-AES to decrypt the ciphertext  $C$  with the secret key  $key$ . Both  $C$  and  $key$  must be  $2 \times 2$  matrices over the finite field  $\mathbb{F}_{2^4}$ . Let  $\gamma$  denote the operation of nibble-sub,  $\pi$  denote shift-row,  $\theta$  denote mix-column, and  $\sigma_{K_i}$  denote add-key with the round key  $K_i$ . Then decryption  $D$  using Phan's Mini-AES is the function composition

$$D = \sigma_{K_0} \circ \gamma^{-1} \circ \pi \circ \theta \circ \sigma_{K_1} \circ \gamma^{-1} \circ \pi \circ \sigma_{K_2}$$

where  $\gamma^{-1}$  is the nibble-sub operation that uses the S-box for decryption, and the order of execution is from right to left.

INPUT:

- $C$  – a ciphertext block; must be a  $2 \times 2$  matrix over the finite field  $\mathbb{F}_{2^4}$
- $key$  – a secret key for this Mini-AES block cipher; must be a  $2 \times 2$  matrix over the finite field  $\mathbb{F}_{2^4}$

OUTPUT:

- The plaintext corresponding to  $C$ .

EXAMPLES:

We encrypt a plaintext, decrypt the ciphertext, then compare the decrypted plaintext with the original plaintext. Here we work with elements of  $\mathbb{F}_{2^4}$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: MS = MatrixSpace(K, 2, 2)
sage: P = MS([ [K("x^3 + 1"), K("x^2 + x")], [K("x^3 + x^2"), K("x + 1")] ]); P

[ x^3 + 1  x^2 + x]
[x^3 + x^2  x + 1]
sage: key = MS([ [K("x^3 + x^2"), K("x^3 + x^2 + x + 1")], [K("x + 1"), K("0")] ]
↔]); key

[      x^3 + x^2  x^3 + x^2 + x + 1]
[      x + 1      0]
sage: C = maes.encrypt(P, key); C
[      x + 1      x^2 + 1]
[x^3 + x^2 + x + 1  x^2]
sage: plaintext = maes.decrypt(C, key)
sage: plaintext; P

[ x^3 + 1  x^2 + x]
[x^3 + x^2  x + 1]

[ x^3 + 1  x^2 + x]
[x^3 + x^2  x + 1]
sage: plaintext == P
True
```

But we can also work with binary strings:

```
sage: bin = BinaryStrings()
sage: P = bin.encoding("de"); P
0110010001100101
sage: P = MS(maes.binary_to_GF(P)); P

[x^2 + x      x^2]
[x^2 + x x^2 + 1]
sage: key = bin.encoding("ke"); key
0110101101100101
sage: key = MS(maes.binary_to_GF(key)); key

[      x^2 + x x^3 + x + 1]
[      x^2 + x      x^2 + 1]
sage: C = maes.encrypt(P, key)
sage: plaintext = maes.decrypt(C, key)
sage: plaintext == P
True
```

Here we work with integers  $n$  such that  $0 \leq n \leq 15$ :

```
sage: P = [3, 5, 7, 14]; P
[3, 5, 7, 14]
sage: key = [2, 6, 7, 8]; key
[2, 6, 7, 8]
sage: P = MS(maes.integer_to_GF(P)); P

[      x + 1      x^2 + 1]
[ x^2 + x + 1 x^3 + x^2 + x]
sage: key = MS(maes.integer_to_GF(key)); key

[      x      x^2 + x]
[x^2 + x + 1      x^3]
sage: C = maes.encrypt(P, key)
sage: plaintext = maes.decrypt(C, key)
sage: plaintext == P
True
```

### **encrypt**( $P, key$ )

Use Phan's Mini-AES to encrypt the plaintext  $P$  with the secret key  $key$ . Both  $P$  and  $key$  must be  $2 \times 2$  matrices over the finite field  $\mathbf{F}_{2^4}$ . Let  $\gamma$  denote the operation of nibble-sub,  $\pi$  denote shift-row,  $\theta$  denote mix-column, and  $\sigma_{K_i}$  denote add-key with the round key  $K_i$ . Then encryption  $E$  using Phan's Mini-AES is the function composition

$$E = \sigma_{K_2} \circ \pi \circ \gamma \circ \sigma_{K_1} \circ \theta \circ \pi \circ \gamma \circ \sigma_{K_0}$$

where the order of execution is from right to left. Note that  $\gamma$  is the nibble-sub operation that uses the S-box for encryption.

INPUT:

- $P$  – a plaintext block; must be a  $2 \times 2$  matrix over the finite field  $\mathbf{F}_{2^4}$
- $key$  – a secret key for this Mini-AES block cipher; must be a  $2 \times 2$  matrix over the finite field  $\mathbf{F}_{2^4}$

OUTPUT:

- The ciphertext corresponding to P.

EXAMPLES:

Here we work with elements of  $\mathbb{F}_{2^4}$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: MS = MatrixSpace(K, 2, 2)
sage: P = MS([ [K("x^3 + 1"), K("x^2 + x")], [K("x^3 + x^2"), K("x + 1")] ]); P

[ x^3 + 1  x^2 + x]
[x^3 + x^2  x + 1]
sage: key = MS([ [K("x^3 + x^2"), K("x^3 + x^2 + x + 1")], [K("x + 1"), K("0")] ]
↪); key

[      x^3 + x^2  x^3 + x^2 + x + 1]
[      x + 1      0]
sage: maes.encrypt(P, key)
[      x + 1      x^2 + 1]
[x^3 + x^2 + x + 1  x^2]
```

But we can also work with binary strings:

```
sage: bin = BinaryStrings()
sage: P = bin.encoding("de"); P
0110010001100101
sage: P = MS(maes.binary_to_GF(P)); P

[x^2 + x  x^2]
[x^2 + x  x^2 + 1]
sage: key = bin.encoding("ke"); key
0110101101100101
sage: key = MS(maes.binary_to_GF(key)); key

[ x^2 + x  x^3 + x + 1]
[ x^2 + x  x^2 + 1]
sage: C = maes.encrypt(P, key)
sage: plaintext = maes.decrypt(C, key)
sage: plaintext == P
True
```

Now we work with integers  $n$  such that  $0 \leq n \leq 15$ :

```
sage: P = [1, 5, 8, 12]; P
[1, 5, 8, 12]
sage: key = [5, 9, 15, 0]; key
[5, 9, 15, 0]
sage: P = MS(maes.integer_to_GF(P)); P

[      1  x^2 + 1]
[      x^3  x^3 + x^2]
sage: key = MS(maes.integer_to_GF(key)); key
```

(continues on next page)

(continued from previous page)

```
[
      x^2 + 1          x^3 + 1]
[x^3 + x^2 + x + 1    0]
sage: C = maes.encrypt(P, key)
sage: plaintext = maes.decrypt(C, key)
sage: plaintext == P
True
```

**integer\_to\_GF(N)**

Return the finite field representation of  $N$ . If  $N$  is an integer such that  $0 \leq N \leq 15$ , return the element of  $\mathbf{F}_{2^4}$  that represents  $N$ . If  $N$  is a list of integers each of which is  $\geq 0$  and  $\leq 15$ , then obtain the element of  $\mathbf{F}_{2^4}$  that represents each such integer, and return a list of such finite field representations. Each integer between 0 and 15, inclusive, can be associated with a unique element of  $\mathbf{F}_{2^4}$  according to the following table:

| integer | $\mathbf{F}_{2^4}$ | integer | $\mathbf{F}_{2^4}$  |
|---------|--------------------|---------|---------------------|
| 0       | 0                  | 8       | $x^3$               |
| 1       | 1                  | 9       | $x^3 + 1$           |
| 2       | $x$                | 10      | $x^3 + x$           |
| 3       | $x + 1$            | 11      | $x^3 + x + 1$       |
| 4       | $x^2$              | 12      | $x^3 + x^2$         |
| 5       | $x^2 + 1$          | 13      | $x^3 + x^2 + 1$     |
| 6       | $x^2 + x$          | 14      | $x^3 + x^2 + x$     |
| 7       | $x^2 + x + 1$      | 15      | $x^3 + x^2 + x + 1$ |

INPUT:

- $N$  – a non-negative integer less than or equal to 15, or a list of such integers

OUTPUT:

- Elements of the finite field  $\mathbf{F}_{2^4}$ .

EXAMPLES:

Obtain the element of  $\mathbf{F}_{2^4}$  representing an integer  $n$ , where  $0 \leq n \leq 15$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: maes.integer_to_GF(0)
0
sage: maes.integer_to_GF(2)
x
sage: maes.integer_to_GF(7)
x^2 + x + 1
```

Obtain the finite field elements corresponding to all non-negative integers less than or equal to 15:

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: lst = [n for n in range(16)]; lst
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]
sage: maes.integer_to_GF(lst)

[0,
 1,
 x,
```

(continues on next page)

(continued from previous page)

```

x + 1,
x^2,
x^2 + 1,
x^2 + x,
x^2 + x + 1,
x^3,
x^3 + 1,
x^3 + x,
x^3 + x + 1,
x^3 + x^2,
x^3 + x^2 + 1,
x^3 + x^2 + x,
x^3 + x^2 + x + 1]

```

**integer\_to\_binary(*N*)**

Return the binary representation of *N*. If *N* is an integer such that  $0 \leq N \leq 15$ , return the binary representation of *N*. If *N* is a list of integers each of which is  $\geq 0$  and  $\leq 15$ , then obtain the binary representation of each integer, and concatenate the individual binary representations into a single binary string. Each integer between 0 and 15, inclusive, can be associated with a unique 4-bit string according to the following table:

| 4-bit string | integer | 4-bit string | integer |
|--------------|---------|--------------|---------|
| 0000         | 0       | 1000         | 8       |
| 0001         | 1       | 1001         | 9       |
| 0010         | 2       | 1010         | 10      |
| 0011         | 3       | 1011         | 11      |
| 0100         | 4       | 1100         | 12      |
| 0101         | 5       | 1101         | 13      |
| 0110         | 6       | 1110         | 14      |
| 0111         | 7       | 1111         | 15      |

INPUT:

- *N* – a non-negative integer less than or equal to 15, or a list of such integers

OUTPUT:

- A binary string representing *N*.

EXAMPLES:

The binary representations of all integers between 0 and 15, inclusive:

```

sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: lst = [n for n in range(16)]; lst
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]
sage: maes.integer_to_binary(lst)
00000000100100011010001010110011110001001101010111100110111101111

```

The binary representation of an integer between 0 and 15, inclusive:

```

sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: maes.integer_to_binary(3)
0011

```

(continues on next page)

(continued from previous page)

```
sage: maes.integer_to_binary(5)
0101
sage: maes.integer_to_binary(7)
0111
```

**mix\_column**(*block*)

Return the matrix multiplication of *block* with a constant matrix. The constant matrix is

$$\begin{bmatrix} x + 1 & x \\ x & x + 1 \end{bmatrix}$$

If the input block is

$$\begin{bmatrix} c_0 & c_2 \\ c_1 & c_3 \end{bmatrix}$$

then the output block is

$$\begin{bmatrix} d_0 & d_2 \\ d_1 & d_3 \end{bmatrix} = \begin{bmatrix} x + 1 & x \\ x & x + 1 \end{bmatrix} \begin{bmatrix} c_0 & c_2 \\ c_1 & c_3 \end{bmatrix}$$

INPUT:

- *block* – a  $2 \times 2$  matrix with entries over  $\mathbf{F}_{2^4}$

OUTPUT:

- A  $2 \times 2$  matrix resulting from multiplying the above constant matrix with the input matrix *block*.

EXAMPLES:

Here we work with elements of  $\mathbf{F}_{2^4}$ :

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: MS = MatrixSpace(K, 2, 2)
sage: mat = MS([ [K("x^2 + x + 1"), K("x^3 + x^2 + 1")], [K("x^3"), K("x")] ])
sage: maes.mix_column(mat)

[      x^3 + x      0]
[      x^2 + 1 x^3 + x^2 + x + 1]
```

Multiplying by the identity matrix should leave the constant matrix unchanged:

```
sage: eye = MS([ [K("1"), K("0")], [K("0"), K("1")] ])
sage: maes.mix_column(eye)

[x + 1    x]
[  x x + 1]
```

We can also work with binary strings:

```
sage: bin = BinaryStrings()
sage: B = bin.encoding("rT"); B
0111001001010100
```

(continues on next page)

(continued from previous page)

```

sage: B = MS(maes.binary_to_GF(B)); B

[x^2 + x + 1      x]
[  x^2 + 1      x^2]
sage: maes.mix_column(B)

[  x + 1 x^3 + x^2 + x]
[          1      x^3]
    
```

We can also work with integers  $n$  such that  $0 \leq n \leq 15$ :

```

sage: P = [10, 5, 2, 7]; P
[10, 5, 2, 7]
sage: P = MS(maes.integer_to_GF(P)); P

[  x^3 + x      x^2 + 1]
[          x x^2 + x + 1]
sage: maes.mix_column(P)

[x^3 + 1      1]
[  1      x + 1]
    
```

**nibble\_sub**(*block*, *algorithm*='encrypt')

Substitute a nibble (or a block of 4 bits) using the following S-box:

| Input | Output | Input | Output |
|-------|--------|-------|--------|
| 0000  | 1110   | 1000  | 0011   |
| 0001  | 0100   | 1001  | 1010   |
| 0010  | 1101   | 1010  | 0110   |
| 0011  | 0001   | 1011  | 1100   |
| 0100  | 0010   | 1100  | 0101   |
| 0101  | 1111   | 1101  | 1001   |
| 0110  | 1011   | 1110  | 0000   |
| 0111  | 1000   | 1111  | 0111   |

The values in the above S-box are taken from the first row of the first S-box of the Data Encryption Standard (DES). Each nibble can be thought of as an element of the finite field  $\mathbb{F}_{2^4}$  of 16 elements. Thus in terms

of  $\mathbb{F}_{2^4}$ , the S-box can also be specified as:

| Input               | Output              |
|---------------------|---------------------|
| 0                   | $x^3 + x^2 + x$     |
| 1                   | $x^2$               |
| $x$                 | $x^3 + x^2 + 1$     |
| $x + 1$             | 1                   |
| $x^2$               | $x$                 |
| $x^2 + 1$           | $x^3 + x^2 + x + 1$ |
| $x^2 + x$           | $x^3 + x + 1$       |
| $x^2 + x + 1$       | $x^3$               |
| $x^3$               | $x + 1$             |
| $x^3 + 1$           | $x^3 + x$           |
| $x^3 + x$           | $x^2 + x$           |
| $x^3 + x + 1$       | $x^3 + x^2$         |
| $x^3 + x^2$         | $x^2 + 1$           |
| $x^3 + x^2 + 1$     | $x^3 + 1$           |
| $x^3 + x^2 + x$     | 0                   |
| $x^3 + x^2 + x + 1$ | $x^2 + x + 1$       |

Note that the above S-box is used for encryption. The S-box for decryption is obtained from the above S-box by reversing the role of the Input and Output columns. Thus the previous Input column for encryption now becomes the Output column for decryption, and the previous Output column for encryption is now the Input column for decryption. The S-box used for decryption can be specified as:

| Input               | Output              |
|---------------------|---------------------|
| 0                   | $x^3 + x^2 + x$     |
| 1                   | $x + 1$             |
| $x$                 | $x^2$               |
| $x + 1$             | $x^3$               |
| $x^2$               | 1                   |
| $x^2 + 1$           | $x^3 + x^2$         |
| $x^2 + x$           | $x^3 + x$           |
| $x^2 + x + 1$       | $x^3 + x^2 + x + 1$ |
| $x^3$               | $x^2 + x + 1$       |
| $x^3 + 1$           | $x^3 + x^2 + 1$     |
| $x^3 + x$           | $x^3 + 1$           |
| $x^3 + x + 1$       | $x^2 + x$           |
| $x^3 + x^2$         | $x^3 + x + 1$       |
| $x^3 + x^2 + 1$     | $x$                 |
| $x^3 + x^2 + x$     | 0                   |
| $x^3 + x^2 + x + 1$ | $x^2 + 1$           |

INPUT:

- **block** – a  $2 \times 2$  matrix with entries over  $\mathbb{F}_{2^4}$
- **algorithm** – (default: "encrypt") a string; a flag to signify whether this nibble-sub operation is used for encryption or decryption. The encryption flag is "encrypt" and the decryption flag is "decrypt".

OUTPUT:

- A  $2 \times 2$  matrix resulting from applying an S-box on entries of the  $2 \times 2$  matrix **block**.

EXAMPLES:

Here we work with elements of the finite field  $\mathbb{F}_{2^4}$ :

```

sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: MS = MatrixSpace(K, 2, 2)
sage: mat = MS([[K("x^3 + x^2 + x + 1"), K("0")], [K("x^2 + x + 1"), K("x^3 + x
↪")]])
sage: maes.nibble_sub(mat, algorithm="encrypt")

[ x^2 + x + 1 x^3 + x^2 + x]
[          x^3          x^2 + x]

```

But we can also work with binary strings:

```

sage: bin = BinaryStrings()
sage: B = bin.encoding("bi"); B
0110001001101001
sage: B = MS(maes.binary_to_GF(B)); B

[x^2 + x      x]
[x^2 + x x^3 + 1]
sage: maes.nibble_sub(B, algorithm="encrypt")

[ x^3 + x + 1 x^3 + x^2 + 1]
[ x^3 + x + 1      x^3 + x]
sage: maes.nibble_sub(B, algorithm="decrypt")

[      x^3 + x      x^2]
[      x^3 + x x^3 + x^2 + 1]

```

Here we work with integers  $n$  such that  $0 \leq n \leq 15$ :

```

sage: P = [2, 6, 8, 14]; P
[2, 6, 8, 14]
sage: P = MS(maes.integer_to_GF(P)); P

[          x      x^2 + x]
[          x^3 x^3 + x^2 + x]
sage: maes.nibble_sub(P, algorithm="encrypt")

[x^3 + x^2 + 1  x^3 + x + 1]
[      x + 1      0]
sage: maes.nibble_sub(P, algorithm="decrypt")

[          x^2      x^3 + x]
[x^2 + x + 1      0]

```

### random\_key()

A random key within the key space of this Mini-AES block cipher. Like the AES, Phan's Mini-AES is a symmetric-key block cipher. A Mini-AES key is a block of 16 bits, or a  $2 \times 2$  matrix with entries over the finite field  $\mathbb{F}_{2^4}$ . Thus the number of possible keys is  $2^{16} = 16^4$ .

OUTPUT:

- A  $2 \times 2$  matrix over the finite field  $\mathbb{F}_{2^4}$ , used as a secret key for this Mini-AES block cipher.

EXAMPLES:

Each nibble of a key is an element of the finite field  $\mathbb{F}_{2^4}$ :

```
sage: K = FiniteField(16, "x")
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: key = maes.random_key()
sage: [key[i][j] in K for i in range(key.nrows()) for j in range(key.ncols())]
[True, True, True, True]
```

Generate a random key, then perform encryption and decryption using that key:

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: MS = MatrixSpace(K, 2, 2)
sage: key = maes.random_key()
sage: P = MS.random_element()
sage: C = maes.encrypt(P, key)
sage: plaintext = maes.decrypt(C, key)
sage: plaintext == P
True
```

**round\_key**(key, n)

Return the round key for round n. Phan's Mini-AES is defined to have two rounds. The round key  $K_0$  is generated and used prior to the first round, with round keys  $K_1$  and  $K_2$  being used in rounds 1 and 2 respectively. In total, there are three round keys, each generated from the secret key key.

INPUT:

- key – the secret key
- n – non-negative integer; the round number

OUTPUT:

- The n-th round key.

EXAMPLES:

Obtaining the round keys from the secret key:

```
sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: MS = MatrixSpace(K, 2, 2)
sage: key = MS([ [K("x^3 + x^2"), K("x^3 + x^2 + x + 1")], [K("x + 1"), K("0")] ]
↵↵)
sage: maes.round_key(key, 0)

[      x^3 + x^2  x^3 + x^2 + x + 1]
[      x + 1      0]
sage: key

[      x^3 + x^2  x^3 + x^2 + x + 1]
[      x + 1      0]
```

(continues on next page)

(continued from previous page)

```

sage: maes.round_key(key, 1)
[x^3 + x x^2 + x]
[x^3 + 1 x^2 + x]
sage: maes.round_key(key, 2)

[ x^2 + 1 x^3 + x]
[x^3 + x^2 x^3 + x^2]

```

**sbox()**

Return the S-box of Mini-AES.

EXAMPLES:

```

sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: maes.sbox()
(14, 4, 13, 1, 2, 15, 11, 8, 3, 10, 6, 12, 5, 9, 0, 7)

```

**shift\_row(block)**

Rotate each row of `block` to the left by different nibble amounts. The first or zero-th row is left unchanged, while the second or row one is rotated left by one nibble. This has the effect of only interchanging the nibbles in the second row. Let  $b_0, b_1, b_2, b_3$  be four nibbles arranged as the following  $2 \times 2$  matrix

$$\begin{bmatrix} b_0 & b_2 \\ b_1 & b_3 \end{bmatrix}$$

Then the operation of shift-row is the mapping

$$\begin{bmatrix} b_0 & b_2 \\ b_1 & b_3 \end{bmatrix} \mapsto \begin{bmatrix} b_0 & b_2 \\ b_3 & b_1 \end{bmatrix}$$

INPUT:

- `block` – a  $2 \times 2$  matrix with entries over  $\mathbb{F}_{2^4}$

OUTPUT:

- A  $2 \times 2$  matrix resulting from applying shift-row on `block`.

EXAMPLES:

Here we work with elements of the finite field  $\mathbb{F}_{2^4}$ :

```

sage: from sage.crypto.block_cipher.miniaes import MiniAES
sage: maes = MiniAES()
sage: K = FiniteField(16, "x")
sage: MS = MatrixSpace(K, 2, 2)
sage: mat = MS([[K("x^3 + x^2 + x + 1"), K("0")], [K("x^2 + x + 1"), K("x^3 + x
↵")]])
sage: maes.shift_row(mat)

[x^3 + x^2 + x + 1      0]
[      x^3 + x      x^2 + x + 1]
sage: mat

[x^3 + x^2 + x + 1      0]
[      x^2 + x + 1      x^3 + x]

```

But we can also work with binary strings:

```

sage: bin = BinaryStrings()
sage: B = bin.encoding("Qt"); B
0101000101110100
sage: B = MS(maes.binary_to_GF(B)); B

[      x^2 + 1          1]
[x^2 + x + 1          x^2]
sage: maes.shift_row(B)

[      x^2 + 1          1]
[      x^2 x^2 + x + 1]

```

Here we work with integers  $n$  such that  $0 \leq n \leq 15$ :

```

sage: P = [3, 6, 9, 12]; P
[3, 6, 9, 12]
sage: P = MS(maes.integer_to_GF(P)); P

[      x + 1    x^2 + x]
[ x^3 + 1 x^3 + x^2]
sage: maes.shift_row(P)

[      x + 1    x^2 + x]
[x^3 + x^2    x^3 + 1]

```

## DES

The Data Encryption Standard.

This file implements the Data Encryption Standard and the corresponding key schedule as described in [U.S1999].

This implementation is meant for experimental and educational usage only, do not use it in production code!

EXAMPLES:

Encrypt a message:

```
sage: from sage.crypto.block_cipher.des import DES
sage: des = DES()
sage: P = 0x01A1D6D039776742
sage: K = 0x7CA110454A1A6E57
sage: C = des.encrypt(plaintext=P, key=K); C.hex()
'690f5b0d9a26939b'
```

And decrypt it again:

```
sage: des.decrypt(ciphertext=C, key=K).hex()
'1a1d6d039776742'
```

Have a look at the used round keys:

```
sage: from sage.crypto.block_cipher.des import DES_KS
sage: ks = DES_KS()
sage: [k.hex() for k in ks(0x1F08260D1AC2465E)]
['103049bfb90e',
 '808d40f07bf',
 ...
 '231000f2dd97']
```

Validate the Sample Round Outputs for DES (cf. [KeSm1998] p. 124):

```
sage: from sage.crypto.block_cipher.des import DES
sage: P = 0
sage: K = 0x10316E028C8F3B4A
sage: for r in range(1, 17):
.....:     DES(rounds=r, doFinalRound=False).encrypt(P, K).hex()
'47092b5b'
'47092b5b53f372af'
'53f372af9f1d158b'
...
```

(continues on next page)

(continued from previous page)

```
'3f6c3efd5a1e5228'
sage: DES().encrypt(P, K).hex()
'82dcbafebdeab6602'
```

Change cipher internals:

```
sage: from sage.crypto.sbox import SBox
sage: cipher = DES(rounds=1, doFinalRound=False)
sage: cipher.sboxes = [[SBox(range(16))]*4]*8
sage: cipher.keySchedule = lambda x: [0] # return the 0 key as round key
sage: cipher.encrypt(plaintext=0x1234, key=0x0).hex()
'80004000d08100'
```

AUTHORS:

- Lukas Stennes (2019-03-29): initial version

```
class sage.crypto.block_cipher.des.DES(rounds=None, keySchedule='DES_KS', keySize=64,
                                         doFinalRound=True)
```

Bases: SageObject

This class implements DES described in [U.S1999].

EXAMPLES:

You can invoke DES encryption/decryption either by calling DES with an appropriate flag:

```
sage: from sage.crypto.block_cipher.des import DES
sage: des = DES()
sage: P = 0x8000000000000000
sage: K = 0x0
sage: C = des(P, K, 'encrypt'); C.hex()
'95f8a5e5dd31d900'
sage: des(C, K, 'decrypt').hex()
'8000000000000000'
```

Or by calling encryption/decryption methods directly:

```
sage: C = des.encrypt(P, K)
sage: P == des.decrypt(C, K)
True
```

The number of rounds can be reduced easily:

```
sage: des = DES(rounds=15)
sage: des(des(P, K, 'encrypt'), K, 'decrypt') == P
True
```

You can use hex (i.e. integers) or a list-like bit representation for the inputs. If the input is an integer the output will be too. If it is list-like the output will be a bit vector:

```
sage: des = DES()
sage: P = vector(GF(2), 64, [1] + [0]*63)
sage: K = vector(GF(2), 64, [0,0,0,0,0,0,0,1]*8)
sage: des.encrypt(P, K)
```

(continues on next page)

(continued from previous page)

```
(1, 0, 0, 1, 0, 1, 0, 1, 1, 1, 1, 1, 1, 0, 0, 0, 1, 0, 1, 0, 0, 1, 0,
 1, 1, 1, 1, 0, 0, 1, 0, 1, 1, 1, 0, 1, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0,
 0, 1, 1, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0)
sage: P = 0x8000000000000000
sage: K = 0x0101010101010101
sage: C = des.encrypt(P, K); C; C.hex()
10806569712552630528
'95f8a5e5dd31d900'
```

**See also:**[DES\\_KS sage.crypto.sboxes](#)`__init__(rounds=None, keySchedule='DES_KS', keySize=64, doFinalRound=True)`

Construct an instance of DES.

INPUT:

- `rounds` – integer (default: `None`); the number of rounds. If `None` the number of rounds of the key schedule is used.
- `keySchedule` – (default: `'DES_KS'`); the key schedule that will be used for encryption and decryption. If `'DES_KS'` the default DES key schedule is used.
- `keySize` – (default: 64); the key length in bits. Must be 56 or 64. In the latter case the key contains 8 parity bits.
- `doFinalRound` – boolean (default: `True`); if `False` a swap takes places but the inverse initial permutation is omitted (i.e. you can get the state after rounds). This only effects encryption.

EXAMPLES:

```
sage: from sage.crypto.block_cipher.des import DES
sage: DES() # indirect doctest
DES block cipher with 16 rounds and the following key schedule:
Original DES key schedule with 16 rounds
```

Reducing the number of rounds is simple. But increasing it is only possible if the key schedule can produce enough round keys:

```
sage: DES(rounds=11) # indirect doctest
DES block cipher with 11 rounds and the following key schedule:
Original DES key schedule with 16 rounds
sage: DES(rounds=42) # indirect doctest
Traceback (most recent call last):
...
ValueError: number of rounds must be less or equal to the number
of rounds of the key schedule
```

You can use arbitrary key schedules. Since it is the only one implemented here the original key schedule is used for demonstration:

```
sage: from sage.crypto.block_cipher.des import DES_KS
sage: DES(keySchedule=DES_KS(11)) # indirect doctest
DES block cipher with 11 rounds and the following key schedule:
Original DES key schedule with 11 rounds
```

`__call__(block, key, algorithm='encrypt')`

Apply DES encryption or decryption on `block` using `key`. The flag `algorithm` controls what action is to be performed on `block`.

INPUT:

- `block` – integer or bit list-like; the plaintext or ciphertext
- `key` – integer or bit list-like; the key
- `algorithm` – string (default: 'encrypt'); a flag to signify whether encryption or decryption is to be applied to `block`. The encryption flag is 'encrypt' and the decryption flag is 'decrypt'

OUTPUT:

- The plaintext or ciphertext corresponding to `block`, obtained using `key`. If `block` is an integer the output will be too. If `block` is list-like the output will be a bit vector.

EXAMPLES:

```
sage: from sage.crypto.block_cipher.des import DES
sage: des = DES()
sage: P = 0x480D39006EE762F2
sage: K = 0x025816164629B007
sage: des(P, K, 'encrypt').hex()
'a1f9915541020b56'
```

`decrypt(ciphertext, key)`

Return the plaintext corresponding to `ciphertext`, using DES decryption with `key`.

INPUT:

- `ciphertext` – integer or bit list-like; the ciphertext that will be decrypted
- `key` – integer or bit list-like; the key

OUTPUT:

- The plaintext corresponding to `ciphertext`, obtained using `key`. If `ciphertext` is an integer the output will be too. If `ciphertext` is list-like the output will be a bit vector.

EXAMPLES:

Decrypt a message:

```
sage: from sage.crypto.block_cipher.des import DES
sage: des = DES()
sage: K64 = 0x7CA110454A1A6E57
sage: C = 0x690F5B0D9A26939B
sage: P = des.decrypt(C, K64).hex(); P
'1a1d6d039776742'
```

You can also use 56 bit keys i.e. you can leave out the parity bits:

```
sage: K56 = 0x7D404224A35BAB
sage: des = DES(keySize=56)
sage: des.decrypt(C, K56).hex() == P
True
```

**encrypt**(*plaintext*, *key*)

Return the ciphertext corresponding to *plaintext*, using DES encryption with *key*.

INPUT:

- *plaintext* – integer or bit list-like; the plaintext that will be encrypted.
- *key* – integer or bit list-like; the key

OUTPUT:

- The ciphertext corresponding to *plaintext*, obtained using *key*. If *plaintext* is an integer the output will be too. If *plaintext* is list-like the output will be a bit vector.

EXAMPLES:

Encrypt a message:

```
sage: from sage.crypto.block_cipher.des import DES
sage: des = DES()
sage: K64 = 0x133457799BBCDF1
sage: P = 0x0123456789ABCDEF
sage: C = des.encrypt(P, K64); C.hex()
'85e813540f0ab405'
```

You can also use 56 bit keys i.e. you can leave out the parity bits:

```
sage: K56 = 0x12695BC9B7B7F8
sage: des = DES(keySize=56)
sage: des.encrypt(P, K56) == C
True
```

**round**(*state*, *round\_key*)

Apply one round of DES to *state* and return the result.

EXAMPLES:

```
sage: from sage.crypto.block_cipher.des import DES
sage: from sage.crypto.block_cipher.des import convert_to_vector
sage: des = DES()
sage: k1 = convert_to_vector(0xFFFFFFFF, 48)
sage: state = convert_to_vector(0xFFFFFFFF11111111, 64)
sage: ZZ(list(des.round(state, k1))[:-1], 2).hex()
'11111111b29684b8'
```

**sbox\_layer**(*block*)

Apply the Sboxes to *block*.

EXAMPLES:

```
sage: from sage.crypto.block_cipher.des import DES
sage: des = DES()
sage: B = vector(GF(2), 48, [0,1,1,0,0,0,0,1,0,0,0,1,0,1,1,1,1,0,1,
.....: 1,1,0,1,0,1,0,0,0,0,1,1,0,0,1,1,0,0,1,
.....: 0,1,0,0,1,0,0,1,1,1])
sage: des.sbox_layer(B)
(0, 1, 0, 1, 1, 1, 0, 0, 1, 0, 0, 0, 0, 1, 0, 1, 0, 1, 1, 0, 1,
0, 1, 1, 0, 0, 1, 0, 1, 1, 1)
```

See also:

[sage.crypto.sboxes](#)

**class** `sage.crypto.block_cipher.des.DES_KS`(*rounds=16, masterKey=None*)

Bases: `SageObject`

This class implements the DES key schedules described in [U.S1999].

EXAMPLES:

Initialise the key schedule with a *masterKey* to use it as an iterable:

```
sage: from sage.crypto.block_cipher.des import DES_KS
sage: ks = DES_KS(masterKey=0)
sage: ks[0]
0
sage: ks[15]
0
```

Or omit the *masterKey* and pass a key when calling the key schedule:

```
sage: ks = DES_KS()
sage: K = ks(0x584023641ABA6176)
sage: K[0].hex()
'd0a2ed2fa124'
sage: K[15].hex()
'43b42af81183'
```

See also:

[DES](#)

**\_\_init\_\_**(*rounds=16, masterKey=None*)

Construct an instance of `DES_KS`.

INPUT:

- *rounds* – integer (default: 16); the number of rounds `self` can create keys for
- *masterKey* – integer or bit list-like (default: `None`); the 64-bit key that will be used

EXAMPLES:

```
sage: from sage.crypto.block_cipher.des import DES_KS
sage: DES_KS()
Original DES key schedule with 16 rounds
```

---

**Note:** If you want to use a `DES_KS` object as an iterable you have to pass a *masterKey* value on initialisation. Otherwise you can omit *masterKey* and pass a key when you call the object.

---

**\_\_call\_\_**(*key*)

Return all round keys in a list.

INPUT:

- *key* – integer or bit list-like; the 64-bit key

OUTPUT:

- A list containing the round keys. If `key` is an integer the elements of the output list will be too. If `key` is list-like the element of the output list will be bit vectors.

## EXAMPLES:

This implementation is using bit vectors for all internal representations. So you can invoke the key schedule with a bit vector:

```
sage: from sage.crypto.block_cipher.des import DES_KS
sage: K = vector(GF(2), [0,0,0,1,0,0,1,1,0,0,1,1,0,1,0,0,0,1,0,1,0,
.....:                    1,1,1,0,1,1,1,1,0,0,1,1,0,0,1,1,0,1,1,1,0,
.....:                    1,1,1,1,0,0,1,1,0,1,1,1,1,1,1,1,1,1,0,0,0,1])
sage: ks = DES_KS(16, K)
sage: [k for k in ks]
[(0, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0, 0, 0, 0, 1, 0, 1, 1, 1, 0, 1, 1,
 1, 1, 1, 1, 1, 1, 1, 1, 0, 0, 0, 1, 1, 1, 0, 0, 0, 0, 0, 1, 1, 1,
 0, 0, 1, 0),
(0, 1, 1, 1, 1, 0, 0, 1, 1, 0, 1, 0, 1, 1, 1, 0, 1, 1, 0, 1, 1, 0,
 0, 1, 1, 1, 0, 1, 1, 0, 1, 1, 1, 1, 0, 0, 1, 0, 0, 1, 1, 1, 1, 0,
 0, 1, 0, 1),
...
(1, 1, 0, 0, 1, 0, 1, 1, 0, 0, 1, 1, 1, 1, 0, 1, 1, 0, 0, 0, 1, 0,
 1, 1, 0, 0, 0, 0, 1, 1, 1, 0, 0, 0, 0, 1, 0, 1, 1, 1, 1, 1, 1, 1,
 0, 1, 0, 1)]
```

But of course you can invoke it with hex representation as well:

```
sage: K = 0x133457799bbcdff1
sage: ks = DES_KS(16, K)
sage: [k.hex() for k in ks]
['1b02effc7072',
 '79aed9dbc9e5',
...
 'cb3d8b0e17f5']
```

**Note:** If you want to use a `DES_KS` object as an iterable you have to pass a `masterKey` value on initialization. Otherwise you can omit `masterKey` and pass a key when you call the object.

`sage.crypto.block_cipher.des.convert_to_vector(I, L)`

Convert `I` to a bit vector of length `L`.

INPUT:

- `I` – integer or bit list-like
- `L` – integer; the desired bit length of the output

OUTPUT:

- the `L`-bit vector representation of `I`

EXAMPLES:

```
sage: from sage.crypto.block_cipher.des import convert_to_vector
sage: convert_to_vector(0x1F, 8)
(0, 0, 0, 1, 1, 1, 1, 1)
```

(continues on next page)

(continued from previous page)

```
sage: v = vector(GF(2), 4, [1,0,1,0])
sage: convert_to_vector(v, 4)
(1, 0, 1, 0)
```

## PRESENT

An ultra-lightweight block cipher.

This file implements the PRESENT block cipher and the corresponding key schedule as described in [BKLPPRSV2007]. PRESENT is an example of an SP-network and consists of 31 rounds. The block length is 64 bits and two key lengths of 80 and 128 bits are supported.

This implementation is meant for experimental and educational usage only, do not use it in production code!

EXAMPLES:

Encrypt a message:

```
sage: from sage.crypto.block_cipher.present import PRESENT
sage: present = PRESENT()
sage: present.encrypt(plaintext=0, key=0).hex()
'2844b365c06992a3'
```

And decrypt it again:

```
sage: present.decrypt(ciphertext=0x2844b365c06992a3, key=0)
0
```

Have a look at the used round keys:

```
sage: from sage.crypto.block_cipher.present import PRESENT_KS
sage: ks = PRESENT_KS()
sage: [k.hex() for k in ks(0)]
['0',
 'c0000000000000000000',
 ...
 '6dab31744f41d700']
```

Tweak around with the cipher:

```
sage: from sage.crypto.sbox import SBox
sage: cipher = PRESENT(rounds=1, doFinalRound=False)
sage: cipher.sbox = SBox(range(16))
sage: cipher.keySchedule = lambda x: [0, 0] # return the 0 keys as round keys
sage: cipher.encrypt(plaintext=0x1234, key=0x0).hex()
'1234'
```

AUTHORS:

- Lukas Stennes (2019-02-01): initial version

`class sage.crypto.block_cipher.present.PRESENT(keySchedule=80, rounds=None, doFinalRound=False)`

Bases: SageObject

This class implements PRESENT described in [BKLPPRSV2007].

EXAMPLES:

You can invoke PRESENT encryption/decryption either by calling PRESENT with an appropriate flag:

```
sage: from sage.crypto.block_cipher.present import PRESENT
sage: present = PRESENT()
sage: P = 0xFFFFFFFFFFFFFFFF
sage: K = 0x0
sage: present(present(P, K, 'encrypt'), K, 'decrypt') == P
True
```

Or by calling encryption/decryption methods directly:

```
sage: C = present.encrypt(P, K)
sage: P == present.decrypt(C, K)
True
```

The number of rounds can be reduced easily:

```
sage: present = PRESENT(rounds=15)
sage: present(present(P, K, 'encrypt'), K, 'decrypt') == P
True
```

You can use integers or a list-like bit representation for the inputs. If the input is an integer the output will be too. If it is list-like the output will be a bit vector:

```
sage: P = ZZ(0).digits(2, padto=64)
sage: K = ZZ(0).digits(2, padto=80)
sage: list(present(present(P, K, 'encrypt'), K, 'decrypt')) == P
True
sage: P = ZZ(0).digits(2, padto=64)
sage: K = 0x0
sage: list(present(present(P, K, 'encrypt'), K, 'decrypt')) == P
True
```

The 80-bit version of PRESENT is used by default but the 128-bit version is also implemented:

```
sage: present = PRESENT(128)
sage: P = 0x0123456789abcdef
sage: K = 0x00112233445566778899aabbccddeeff
sage: present(present(P, K, 'encrypt'), K, 'decrypt') == P
True
```

See also:

[PRESENT\\_KS](#) `sage.crypto.sboxes`

`__init__(keySchedule=80, rounds=None, doFinalRound=False)`

Construct an instance of PRESENT.

INPUT:

- `keySchedule` – (default: 80); the key schedule that will be used for encryption and decryption. Use 80 or 128 as a shortcut for the original key schedules from [BKLPPRSV2007].
- `rounds` – integer (default: None); the number of rounds. If None the number of rounds of the key schedule is used.
- `doFinalRound` – boolean (default: False); flag to control whether the linear layer in the last round should take place or not. Since the last linear layer does not add any security, it usually does not take place in real world implementations for performance reasons.

EXAMPLES:

By default a 80-bit version with 31 rounds is created:

```
sage: from sage.crypto.block_cipher.present import PRESENT
sage: PRESENT() # indirect doctest
PRESENT block cipher with 31 rounds, deactivated linear layer in
last round and the following key schedule:
Original PRESENT key schedule with 80-bit keys and 31 rounds
```

The 128-bit version is also implemented:

```
sage: PRESENT(128) # indirect doctest
PRESENT block cipher with 31 rounds, deactivated linear layer in
last round and the following key schedule:
Original PRESENT key schedule with 128-bit keys and 31 rounds
```

Reducing the number of rounds is simple. But increasing it is not possible:

```
sage: PRESENT(keySchedule=80, rounds=23) # indirect doctest
PRESENT block cipher with 23 rounds, deactivated linear layer in
last round and the following key schedule:
Original PRESENT key schedule with 80-bit keys and 31 rounds
sage: PRESENT(80, 32) # indirect doctest
Traceback (most recent call last):
...
ValueError: number of rounds must be less or equal to the number
of rounds of the key schedule
```

By default the linear layer operation in the last round is omitted but of course you can enable it:

```
sage: PRESENT(doFinalRound=True) # indirect doctest
PRESENT block cipher with 31 rounds, activated linear layer in
last round and the following key schedule:
Original PRESENT key schedule with 80-bit keys and 31 rounds
```

You can use arbitrary key schedules. Since it is the only one implemented here the original key schedule is used for demonstration:

```
sage: from sage.crypto.block_cipher.present import PRESENT_KS
sage: PRESENT(keySchedule=PRESENT_KS(80, 15)) # indirect doctest
PRESENT block cipher with 15 rounds, deactivated linear layer in
last round and the following key schedule:
Original PRESENT key schedule with 80-bit keys and 15 rounds
```

**See also:**

[PRESENT\\_KS](#)

`__call__`(*block*, *key*, *algorithm*='encrypt')

Apply PRESENT encryption or decryption on *block* using *key*. The flag *algorithm* controls what action is to be performed on *block*.

INPUT:

- *block* – integer or bit list-like; the plaintext or ciphertext
- *K* – integer or bit list-like; the key
- *algorithm* – string (default: 'encrypt'); a flag to signify whether encryption or decryption is to be applied to *B*. The encryption flag is 'encrypt' and the decryption flag is 'decrypt'

OUTPUT:

- The plaintext or ciphertext corresponding to *block*, obtained using the key. If *block* is an integer the output will be too. If *block* is list-like the output will be a bit vector.

EXAMPLES:

```
sage: from sage.crypto.block_cipher.present import PRESENT
sage: present = PRESENT(doFinalRound=True)
sage: P = 0xFFFFFFFFFFFFFFFF
sage: K = 0x0
sage: present(P, K, 'encrypt').hex()
'a112ffc72f68417b'
```

`decrypt`(*ciphertext*, *key*)

Return the plaintext corresponding to the *ciphertext*, using PRESENT decryption with *key*.

INPUT:

- *ciphertext* – integer or bit list-like; the ciphertext that will be decrypted
- *key* – integer or bit list-like; the key

OUTPUT:

- The plaintext corresponding to *ciphertext*, obtained using the key. If *ciphertext* is an integer the output will be too. If *ciphertext* is list-like the output will be a bit vector.

EXAMPLES:

The test vectors from [BKLPPRSV2007] are checked here:

```
sage: from sage.crypto.block_cipher.present import PRESENT
sage: present = PRESENT(doFinalRound=True)
sage: p1 = 0x0
sage: k1 = 0x0
sage: c1 = 0x5579C1387B228445
sage: present.decrypt(c1, k1) == p1
True
sage: p2 = 0x0
sage: k2 = 0xFFFFFFFFFFFFFFFF
sage: c2 = 0xE72C46C0F5945049
sage: present.decrypt(c2, k2) == p2
True
sage: p3 = 0xFFFFFFFFFFFFFFFF
sage: k3 = 0x0
sage: c3 = 0xA112FFC72F68417B
```

(continues on next page)

(continued from previous page)

```

sage: present.decrypt(c3, k3) == p3
True
sage: p4 = 0xFFFFFFFFFFFFFFFF
sage: k4 = 0xFFFFFFFFFFFFFFFF
sage: c4 = 0x3333DCD3213210D2
sage: present.decrypt(c4, k4) == p4
True

```

**encrypt**(plaintext, key)

Return the ciphertext corresponding to plaintext, using PRESENT encryption with key.

INPUT:

- plaintext – integer or bit list-like; the plaintext that will be encrypted.
- key – integer or bit list-like; the key

OUTPUT:

- The ciphertext corresponding to plaintext, obtained using the key. If plaintext is an integer the output will be too. If plaintext is list-like the output will be a bit vector.

EXAMPLES:

The test vectors from [BKLPPRSV2007] are checked here:

```

sage: from sage.crypto.block_cipher.present import PRESENT
sage: present = PRESENT(doFinalRound=True)
sage: p1 = 0x0
sage: k1 = 0x0
sage: c1 = 0x5579C1387B228445
sage: present.encrypt(p1, k1) == c1
True
sage: p2 = 0x0
sage: k2 = 0xFFFFFFFFFFFFFFFF
sage: c2 = 0xE72C46C0F5945049
sage: present.encrypt(p2, k2) == c2
True
sage: p3 = 0xFFFFFFFFFFFFFFFF
sage: k3 = 0x0
sage: c3 = 0xA112FFC72F68417B
sage: present.encrypt(p3, k3) == c3
True
sage: p4 = 0xFFFFFFFFFFFFFFFF
sage: k4 = 0xFFFFFFFFFFFFFFFF
sage: c4 = 0x3333DCD3213210D2
sage: present.encrypt(p4, k4) == c4
True

```

ALGORITHM:

Description of the encryption function based on [BKLPPRSV2007]:

A top-level algorithmic description of PRESENT encryption:

```

generateRoundKeys()
for i = 1 to 31 do

```

(continues on next page)

(continued from previous page)

```

addRoundkey(STATE, K_i)
sBoxLayer(STATE)
pLayer(STATE)
end for
addRoundkey(STATE, K_{32})
    
```

Each of the 31 rounds consists of an XOR operation to introduce a round key  $K_i$  for  $1 \leq i \leq 32$ , where  $K_{32}$  is used for post-whitening, a linear bitwise permutation and a non-linear substitution layer. The non-linear layer uses a single 4-bit S-box which is applied 16 times in parallel in each round. Each stage but addRoundkey is specified in its corresponding function.

**addRoundkey:** Given round key  $K_i = \kappa_{63}^i \dots \kappa_0^i$  for  $1 \leq i \leq 32$  and current STATE  $b_{63} \dots b_0$ , addRoundkey consists of the operation for  $0 \leq j \leq 63$ ,  $b_j = b_j \oplus \kappa_j^i$ .

**linear\_layer**(state, inverse=False)

Apply the pLayer of PRESENT to the bit vector state and return the result.

The bit permutation used in PRESENT is given by the following table. Bit  $i$  of STATE is moved to position  $P(i)$ .

|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| i    | 0  | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 |
| P(i) | 0  | 16 | 32 | 48 | 1  | 17 | 33 | 49 | 2  | 18 | 34 | 50 | 3  | 19 | 35 | 51 |
|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| i    | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
| P(i) | 4  | 20 | 36 | 52 | 5  | 21 | 37 | 53 | 6  | 22 | 38 | 54 | 7  | 23 | 39 | 55 |
|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| i    | 32 | 33 | 34 | 35 | 36 | 37 | 38 | 39 | 40 | 41 | 42 | 43 | 44 | 45 | 46 | 47 |
| P(i) | 8  | 24 | 40 | 56 | 9  | 25 | 41 | 57 | 10 | 26 | 42 | 58 | 11 | 27 | 43 | 59 |
|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| i    | 48 | 49 | 50 | 51 | 52 | 53 | 54 | 55 | 56 | 57 | 58 | 59 | 60 | 61 | 62 | 63 |
| P(i) | 12 | 28 | 44 | 60 | 13 | 29 | 45 | 61 | 14 | 30 | 46 | 62 | 15 | 31 | 47 | 63 |

EXAMPLES:

```

sage: from sage.crypto.block_cipher.present import PRESENT
sage: present = PRESENT()
sage: state = vector(GF(2), 64, [0, 1]+[0]*62)
sage: present.linear_layer(state)
(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0,
0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0)
    
```

**round**(state, round\_counter, round\_key, inverse=False)

Apply one round of PRESENT to state and return the result.

EXAMPLES:

```

sage: from sage.crypto.block_cipher.present import PRESENT
sage: from sage.crypto.block_cipher.present import convert_to_vector
sage: present = PRESENT(128)
sage: k = convert_to_vector(0x0011223344556677, 64)
sage: p = convert_to_vector(0x0123456789abcdef, 64)
    
```

(continues on next page)

(continued from previous page)

```
sage: ZZ(list(present.round(p, 0, k)), 2).hex()
'ad0ed4ca386b6559'
```

`sbox_layer`(*state*, *inverse=False*)

Apply the sBoxLayer of PRESENT to the bit vector *state* and return the result.

The S-box used in PRESENT is a 4-bit to 4-bit S-box. The action of this box in hexadecimal notation is given by the following table.

| x    | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | A | B | C | D | E | F |
|------|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| S[x] | C | 5 | 6 | B | 9 | 0 | A | D | 3 | E | F | 8 | 4 | 7 | 1 | 2 |

For sBoxLayer the current STATE  $b_{63} \dots b_0$  is considered as sixteen 4-bit words  $w_{15} \dots w_0$  where  $w_i = b_{4i+3} || b_{4i+2} || b_{4i+1} || b_{4i}$  for  $0 \leq i \leq 15$  and the output nibble  $S[w_i]$  provides the updated state values in the obvious way.

EXAMPLES:

```
sage: from sage.crypto.block_cipher.present import PRESENT
sage: present = PRESENT()
sage: state = vector(GF(2), 64, [0]*64)
sage: present.sbox_layer(state)
(0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0,
1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1,
0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1)
sage: state = vector(GF(2), 64, [1]+[0]*63)
sage: present.sbox_layer(state)
(1, 0, 1, 0, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0,
1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1,
0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1)
```

**Note:** `sage.crypto.sbox` uses big endian by default whereas most of Sage uses little endian. So to use the big endian PRESENT Sbox from `sage.crypto.sboxes.sboxes.sbox_layer()` has to do some endian conversion (i.e. reverse input and output of the Sbox). Keep this in mind if you change the Sbox or `sbox_layer()`.

**class** `sage.crypto.block_cipher.present.PRESENT_KS`(*keysize=80*, *rounds=31*, *master\_key=None*)

Bases: `SageObject`

This class implements the PRESENT key schedules for both 80-bit and 128-bit keys as described in [BKLPPRSV2007].

EXAMPLES:

Initialise the key schedule with a *master\_key* to use it as an iterable:

```
sage: from sage.crypto.block_cipher.present import PRESENT_KS
sage: ks = PRESENT_KS(master_key=0)
sage: ks[0] == 0x0
True
sage: ks[31] == 0x6dab31744f41d700
True
```

Or omit the *master\_key* and pass a key when calling the key schedule:

```

sage: ks = PRESENT_KS(keysize=128)
sage: K = ks(0x00112233445566778899aabbccddeeff)
sage: K[0] == 0x0011223344556677
True
sage: K[31] == 0x091989a5ae8eab21
True

```

**ALGORITHM:**

Description of the key schedule for 64-bit and 128-bit keys from [BKLPPRSV2007]:

The key schedule for 64-bit keys works as follows:

At round  $i$  the 64-bit round key  $K_i = \kappa_{63}\kappa_{62} \dots \kappa_0$  consists of the 64 leftmost bits of the current contents of register  $K$ . Thus at round  $i$  we have that:

$$K_i = \kappa_{63}\kappa_{62} \dots \kappa_0 = k_{79}k_{78} \dots k_{16}.$$

After extracting the round key  $K_i$ , the key register  $K = k_{79}k_{78} \dots k_0$  is updated as follows:

$$\begin{aligned} [k_{79}k_{78} \dots k_1k_0] &= [k_{18}k_{17} \dots k_{20}k_{19}] \\ [k_{79}k_{78}k_{77}k_{76}] &= S[k_{79}k_{78}k_{77}k_{76}] \\ [k_{19}k_{18}k_{17}k_{16}k_{15}] &= [k_{19}k_{18}k_{17}k_{16}k_{15}] \oplus \text{round\_counter} \end{aligned}$$

Thus, the key register is rotated by 61 bit positions to the left, the left-most four bits are passed through the PRESENT S-box, and the round\_counter value  $i$  is exclusive-ored with bits  $k_{19}k_{18}k_{17}k_{16}k_{15}$  of  $K$  with the least significant bit of round\_counter on the right.

The key schedule for 128-bit keys works as follows:

At round  $i$  the 64-bit round key  $K_i = \kappa_{63}\kappa_{62} \dots \kappa_0$  consists of the 64 leftmost bits of the current contents of register  $K$ . Thus at round  $i$  we have that:

$$K_i = \kappa_{63}\kappa_{62} \dots \kappa_0 = k_{127}k_{126} \dots k_{64}$$

After extracting the round key  $K_i$ , the key register  $K = k_{127}k_{126} \dots k_0$  is updated as follows:

$$\begin{aligned} [k_{127}k_{126} \dots k_1k_0] &= [k_{66}k_{65} \dots k_{68}k_{67}] \\ [k_{127}k_{126}k_{125}k_{124}] &= S[k_{127}k_{126}k_{125}k_{124}] \\ [k_{123}k_{122}k_{121}k_{120}] &= S[k_{123}k_{122}k_{121}k_{120}] \\ [k_{66}k_{65}k_{64}k_{63}k_{62}] &= [k_{66}k_{65}k_{64}k_{63}k_{62}] \oplus \text{round\_counter} \end{aligned}$$

Thus, the key register is rotated by 61 bit positions to the left, the left-most eight bits are passed through two PRESENT S-boxes, and the round\_counter value  $i$  is exclusive-ored with bits  $k_{66}k_{65}k_{64}k_{63}k_{62}$  of  $K$  with the least significant bit of round\_counter on the right.

**See also:**

[\*PRESENT sage.crypto.sboxes\*](#)

---

**Note:** [\*sage.crypto.sbox\*](#) uses big endian by default whereas most of Sage uses little endian. So to use the big endian PRESENT Sbox from [\*sage.crypto.sboxes PRESENT\\_KS\*](#) has to do some endian conversion (i.e. reverse input and output of the Sbox). Keep this in mind if you change the Sbox or `__call__()`.

---

`__init__(keysize=80, rounds=31, master_key=None)`

Construct an instance of PRESENT\_KS.

INPUT:

- `keysize` – integer (default: 80); the size of the keys that will be used in bits. It must be either 80 or 128.
- `rounds` – integer (default: 31); the number of rounds `self` can create keys for
- `master_key` – integer or bit list-like (default: None); the key that will be used

EXAMPLES:

```
sage: from sage.crypto.block_cipher.present import PRESENT_KS
sage: ks = PRESENT_KS()
Original PRESENT key schedule with 80-bit keys and 31 rounds
```

**Note:** If you want to use a PRESENT\_KS object as an iterable you have to pass a `master_key` value on initialisation. Otherwise you can omit `master_key` and pass a key when you call the object.

`__call__(K)`

Return all round keys in a list.

INPUT:

- `K` – integer or bit list-like; the key

OUTPUT:

- A list containing `rounds + 1` round keys. Since `addRoundkey` takes place in every round and after the last round there must be `rounds + 1` round keys. If `K` is an integer the elements of the output list will be too. If `K` is list-like the element of the output list will be bit vectors.

EXAMPLES:

```
sage: from sage.crypto.block_cipher.present import PRESENT_KS
sage: ks = PRESENT_KS()
sage: ks(0)[31] == 0x6dab31744f41d700
True
```

**Note:** If you want to use a PRESENT\_KS object as an iterable you have to pass a `master_key` value on initialisation. Otherwise you can omit `master_key` and pass a key when you call the object.

`sage.crypto.block_cipher.present.convert_to_vector(I, L)`

Convert `I` to a bit vector of length `L`.

INPUT:

- `I` – integer or bit list-like
- `L` – integer; the desired bit length of the output

OUTPUT:

- the `L`-bit vector representation of `I`

EXAMPLES:

```
sage: from sage.crypto.block_cipher.present import convert_to_vector
sage: convert_to_vector(0x1F, 8)
(1, 1, 1, 1, 1, 0, 0, 0)
sage: v = vector(GF(2), 4, [1,0,1,0])
sage: convert_to_vector(v, 4)
(1, 0, 1, 0)
```

## BLUM-GOLDWASSER PROBABILISTIC ENCRYPTION

The Blum-Goldwasser probabilistic public-key encryption scheme. This scheme was originally described in [BG1985]. See also section 8.7.2 of [MvOV1996] and the [Wikipedia article Blum-Goldwasser\\_cryptosystem](#) on this scheme.

AUTHORS:

- Mike Hogan and David Joyner (2009-9-19): initial procedural version released as public domain software.
- Minh Van Nguyen (2009-12): integrate into Sage as a class and relicense under the GPLv2+. Complete rewrite of the original version to follow the description contained in [MvOV1996].

**class** sage.crypto.public\_key.blum\_goldwasser.**BlumGoldwasser**

Bases: *PublicKeyCryptosystem*

The Blum-Goldwasser probabilistic public-key encryption scheme.

The Blum-Goldwasser encryption and decryption algorithms as described in *encrypt()* and *decrypt()*, respectively, make use of the least significant bit of a binary string. A related concept is the  $k$  least significant bits of a binary string. For example, given a positive integer  $n$ , let  $b = b_0b_1 \cdots b_{m-1}$  be the binary representation of  $n$  so that  $b$  is a binary string of length  $m$ . Then the least significant bit of  $n$  is  $b_{m-1}$ . If  $0 < k \leq m$ , then the  $k$  least significant bits of  $n$  are  $b_{m-1}b_{m-k} \cdots b_{m-1}$ . The least significant bit of an integer is also referred to as its parity bit, because this bit determines whether the integer is even or odd. In the following example, we obtain the least significant bit of an integer:

```
sage: n = 123
sage: b = n.binary(); b
'1111011'
sage: n % 2
1
sage: b[-1]
'1'
```

Now find the 4 least significant bits of the integer  $n = 123$ :

```
sage: b
'1111011'
sage: b[-4:]
'1011'
```

The last two examples could be worked through as follows:

```
sage: from sage.crypto.util import least_significant_bits
sage: least_significant_bits(123, 1)
[1]
```

(continues on next page)

(continued from previous page)

```
sage: least_significant_bits(123, 4)
[1, 0, 1, 1]
```

## EXAMPLES:

The following encryption/decryption example is taken from Example 8.57, pages 309–310 of [MvOV1996]:

```
sage: from sage.crypto.public_key.blum_goldwasser import BlumGoldwasser
sage: bg = BlumGoldwasser()
The Blum-Goldwasser public-key encryption scheme.
sage: p = 499; q = 547
sage: pubkey = bg.public_key(p, q); pubkey
272953
sage: prikey = bg.private_key(p, q); prikey
(499, 547, -57, 52)
sage: P = "10011100000100001100"
sage: C = bg.encrypt(P, pubkey, seed=159201); C
([[0, 0, 1, 0], [0, 0, 0, 0], [1, 1, 0, 0], [1, 1, 1, 0], [0, 1, 0, 0]], 139680)
sage: M = bg.decrypt(C, prikey); M
[[1, 0, 0, 1], [1, 1, 0, 0], [0, 0, 0, 1], [0, 0, 0, 0], [1, 1, 0, 0]]
sage: M = "".join(str(x) for x in flatten(M)); M
'10011100000100001100'
sage: M == P
True
```

Generate a pair of random public/private keys. Use the public key to encrypt a plaintext. Then decrypt the resulting ciphertext using the private key. Finally, compare the decrypted message with the original plaintext.

```
sage: from sage.crypto.public_key.blum_goldwasser import BlumGoldwasser
sage: from sage.crypto.util import bin_to_ascii
sage: bg = BlumGoldwasser()
sage: pubkey, prikey = bg.random_key(10**4, 10**6)
sage: P = "A fixed plaintext."
sage: C = bg.encrypt(P, pubkey)
sage: M = bg.decrypt(C, prikey)
sage: bin_to_ascii(flatten(M)) == P
True
```

If  $(p, q, a, b)$  is a private key, then  $n = pq$  is the corresponding public key. Furthermore, we have  $\gcd(p, q) = ap + bq = 1$ .

```
sage: p, q, a, b = prikey
sage: pubkey == p * q
True
sage: gcd(p, q) == a*p + b*q == 1
True
```

**decrypt**( $C, K$ )

Apply the Blum-Goldwasser scheme to decrypt the ciphertext  $C$  using the private key  $K$ .

## INPUT:

- $C$  – a ciphertext resulting from encrypting a plaintext using the Blum-Goldwasser encryption algorithm. The ciphertext  $C$  must be of the form  $C = (c_1, c_2, \dots, c_t, x_{t+1})$ . Each  $c_i$  is a sub-block of binary string and  $x_{t+1}$  is the result of the  $t + 1$ -th iteration of the Blum-Blum-Shub algorithm.

- $K$  – a private key  $(p, q, a, b)$  where  $p$  and  $q$  are distinct Blum primes and  $\gcd(p, q) = ap + bq = 1$ .

OUTPUT:

- The plaintext resulting from decrypting the ciphertext  $C$  using the Blum-Goldwasser decryption algorithm.

ALGORITHM:

The Blum-Goldwasser decryption algorithm is described in Algorithm 8.56, page 309 of [MvOV1996]. The algorithm works as follows:

1. Let  $C$  be the ciphertext  $C = (c_1, c_2, \dots, c_t, x_{t+1})$ . Then  $t$  is the number of ciphertext sub-blocks and  $h$  is the length of each binary string sub-block  $c_i$ .
2. Let  $(p, q, a, b)$  be the private key whose corresponding public key is  $n = pq$ . Note that  $\gcd(p, q) = ap + bq = 1$ .
3. Compute  $d_1 = ((p + 1)/4)^{t+1} \bmod (p - 1)$ .
4. Compute  $d_2 = ((q + 1)/4)^{t+1} \bmod (q - 1)$ .
5. Let  $u = x_{t+1}^{d_1} \bmod p$ .
6. Let  $v = x_{t+1}^{d_2} \bmod q$ .
7. Compute  $x_0 = vap + ubq \bmod n$ .
8. For  $i$  from 1 to  $t$ , do:
  1. Compute  $x_i = x_{i-1}^2 \bmod n$ .
  2. Let  $p_i$  be the  $h$  least significant bits of  $x_i$ .
  3. Compute  $m_i = p_i \oplus c_i$ .
9. The plaintext is  $m = m_1 m_2 \dots m_t$ .

EXAMPLES:

The following decryption example is taken from Example 8.57, pages 309–310 of [MvOV1996]. Here we decrypt a binary string:

```
sage: from sage.crypto.public_key.blum_goldwasser import BlumGoldwasser
sage: bg = BlumGoldwasser()
sage: p = 499; q = 547
sage: C = ([[0, 0, 1, 0], [0, 0, 0, 0], [1, 1, 0, 0], [1, 1, 1, 0], [0, 1, 0, 0],
            [0, 0, 0, 0]], 139680)
sage: K = bg.private_key(p, q); K
(499, 547, -57, 52)
sage: P = bg.decrypt(C, K); P
[[1, 0, 0, 1], [1, 1, 0, 0], [0, 0, 0, 1], [0, 0, 0, 0], [1, 1, 0, 0]]
```

Convert the plaintext sub-blocks into a binary string:

```
sage: bin = BinaryStrings()
sage: bin(flatten(P))
10011100000100001100
```

Decrypt a longer ciphertext and convert the resulting plaintext into an ASCII string:

```

sage: from sage.crypto.public_key.blum_goldwasser import BlumGoldwasser
sage: from sage.crypto.util import bin_to_ascii
sage: bg = BlumGoldwasser()
sage: p = 78307; q = 412487
sage: K = bg.private_key(p, q)
sage: C = ([[1, 1, 0, 0, 1, 0, 1, 0, 0, 1, 0, 0, 0, 1, 0, 0], \
.....: [1, 0, 0, 1, 1, 0, 0, 1, 0, 1, 0, 0, 0, 0, 1, 1], \
.....: [0, 1, 1, 1, 1, 1, 1, 1, 0, 0, 0, 1, 0, 0, 0, 0], \
.....: [0, 0, 1, 1, 0, 0, 1, 0, 0, 1, 1, 1, 1, 0, 1, 1], \
.....: [1, 0, 0, 1, 0, 1, 0, 1, 1, 1, 0, 0, 1, 0, 0, 0], \
.....: [0, 0, 1, 0, 0, 1, 0, 0, 1, 0, 0, 0, 0, 1, 0, 1], \
.....: [1, 1, 1, 0, 0, 1, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0], \
.....: [1, 1, 0, 0, 0, 0, 0, 1, 1, 1, 0, 0, 0, 0, 0, 1], \
.....: [0, 1, 0, 1, 0, 0, 0, 1, 0, 1, 0, 1, 0, 1, 0, 0], \
.....: [1, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 1], \
.....: [1, 1, 1, 0, 0, 1, 1, 1, 0, 1, 0, 1, 0, 1, 0, 1], \
.....: [1, 1, 1, 1, 1, 1, 1, 1, 1, 0, 1, 1, 0, 0, 1, 0], \
.....: [0, 1, 1, 1, 1, 1, 1, 1, 0, 0, 0, 0, 0, 1, 1, 1]], 3479653279)
sage: P = bg.decrypt(C, K)
sage: bin_to_ascii(flatten(P))
'Blum-Goldwasser encryption'

```

**encrypt**( $P$ ,  $K$ ,  $seed=None$ )

Apply the Blum-Goldwasser scheme to encrypt the plaintext  $P$  using the public key  $K$ .

INPUT:

- $P$  – a non-empty string of plaintext. The string "" is an empty string, whereas " " is a string consisting of one white space character. The plaintext can be a binary string or a string of ASCII characters. Where  $P$  is an ASCII string, then  $P$  is first encoded as a binary string prior to encryption.
- $K$  – a public key, which is the product of two Blum primes.
- $seed$  – (default: None) if  $p$  and  $q$  are Blum primes and  $n = pq$  is a public key, then  $seed$  is a quadratic residue in the multiplicative group  $(\mathbf{Z}/n\mathbf{Z})^*$ . If  $seed=None$ , then the function would generate its own random quadratic residue in  $(\mathbf{Z}/n\mathbf{Z})^*$ . Where a value for  $seed$  is provided, it is your responsibility to ensure that the seed is a quadratic residue in the multiplicative group  $(\mathbf{Z}/n\mathbf{Z})^*$ .

OUTPUT:

- The ciphertext resulting from encrypting  $P$  using the public key  $K$ . The ciphertext  $C$  is of the form  $C = (c_1, c_2, \dots, c_t, x_{t+1})$ . Each  $c_i$  is a sub-block of binary string and  $x_{t+1}$  is the result of the  $t + 1$ -th iteration of the Blum-Blum-Shub algorithm.

ALGORITHM:

The Blum-Goldwasser encryption algorithm is described in Algorithm 8.56, page 309 of [MvOV1996]. The algorithm works as follows:

1. Let  $n$  be a public key, where  $n = pq$  is the product of two distinct Blum primes  $p$  and  $q$ .
2. Let  $k = \lfloor \log_2(n) \rfloor$  and  $h = \lfloor \log_2(k) \rfloor$ .
3. Let  $m = m_1 m_2 \cdots m_t$  be the message (plaintext) where each  $m_i$  is a binary string of length  $h$ .
4. Choose a random seed  $x_0$ , which is a quadratic residue in the multiplicative group  $(\mathbf{Z}/n\mathbf{Z})^*$ . That is, choose a random  $r \in (\mathbf{Z}/n\mathbf{Z})^*$  and compute  $x_0 = r^2 \bmod n$ .
5. For  $i$  from 1 to  $t$ , do:

1. Let  $x_i = x_{i-1}^2 \bmod n$ .
2. Let  $p_i$  be the  $h$  least significant bits of  $x_i$ .
3. Let  $c_i = p_i \oplus m_i$ .
6. Compute  $x_{t+1} = x_t^2 \bmod n$ .
7. The ciphertext is  $c = (c_1, c_2, \dots, c_t, x_{t+1})$ .

The value  $h$  in the algorithm is the sub-block length. If the binary string representing the message cannot be divided into blocks of length  $h$  each, then other sub-block lengths would be used instead. The sub-block lengths to fall back on are in the following order: 16, 8, 4, 2, 1.

EXAMPLES:

The following encryption example is taken from Example 8.57, pages 309–310 of [MvOV1996]. Here, we encrypt a binary string:

```
sage: from sage.crypto.public_key.blum_goldwasser import BlumGoldwasser
sage: bg = BlumGoldwasser()
sage: p = 499; q = 547; n = p * q
sage: P = "10011100000100001100"
sage: C = bg.encrypt(P, n, seed=159201); C
([[0, 0, 1, 0], [0, 0, 0, 0], [1, 1, 0, 0], [1, 1, 1, 0], [0, 1, 0, 0]], 139680)
```

Convert the ciphertext sub-blocks into a binary string:

```
sage: bin = BinaryStrings()
sage: bin(flatten(C[0]))
00100000110011100100
```

Now encrypt an ASCII string. The result is random; no seed is provided to the encryption function so the function generates its own random seed:

```
sage: from sage.crypto.public_key.blum_goldwasser import BlumGoldwasser
sage: bg = BlumGoldwasser()
sage: K = 32300619509
sage: P = "Blum-Goldwasser encryption"
sage: bg.encrypt(P, K) # random
([[1, 1, 0, 0, 1, 0, 1, 0, 0, 1, 0, 0, 0, 1, 0, 0], \
 [1, 0, 0, 1, 1, 0, 0, 1, 0, 1, 0, 0, 0, 0, 1, 1], \
 [0, 1, 1, 1, 1, 1, 1, 1, 0, 0, 0, 1, 0, 0, 0, 0], \
 [0, 0, 1, 1, 0, 0, 1, 0, 0, 1, 1, 1, 1, 0, 1, 1], \
 [1, 0, 0, 1, 0, 1, 0, 1, 1, 1, 0, 0, 1, 0, 0, 0], \
 [0, 0, 1, 0, 0, 1, 0, 0, 1, 0, 0, 0, 0, 1, 0, 1], \
 [1, 1, 1, 0, 0, 1, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0], \
 [1, 1, 0, 0, 0, 0, 0, 1, 1, 1, 0, 0, 0, 0, 0, 1], \
 [0, 1, 0, 1, 0, 0, 0, 1, 0, 1, 0, 1, 0, 1, 0, 0], \
 [1, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 1], \
 [1, 1, 1, 0, 0, 1, 1, 1, 0, 1, 0, 1, 0, 1, 0, 1], \
 [1, 1, 1, 1, 1, 1, 1, 1, 1, 0, 1, 1, 0, 0, 1, 0], \
 [0, 1, 1, 1, 1, 1, 1, 1, 0, 0, 0, 0, 0, 1, 1, 1]], 3479653279)
```

### **private\_key(p, q)**

Return the Blum–Goldwasser private key corresponding to the distinct Blum primes  $p$  and  $q$ .

INPUT:

- $p$  – a Blum prime.
- $q$  – a Blum prime.

OUTPUT:

- The Blum-Goldwasser private key  $(p, q, a, b)$  where  $\gcd(p, q) = ap + bq = 1$ .

Both  $p$  and  $q$  must be distinct Blum primes. Let  $p$  be a positive prime. Then  $p$  is a Blum prime if  $p$  is congruent to 3 modulo 4, i.e.  $p \equiv 3 \pmod{4}$ .

EXAMPLES:

Obtain two distinct Blum primes and compute the Blum-Goldwasser private key corresponding to those two Blum primes:

```
sage: from sage.crypto.public_key.blum_goldwasser import BlumGoldwasser
sage: from sage.crypto.util import is_blum_prime
sage: bg = BlumGoldwasser()
sage: P = primes_first_n(10); P
[2, 3, 5, 7, 11, 13, 17, 19, 23, 29]
sage: [is_blum_prime(_) for _ in P]
[False, True, False, True, True, False, False, True, True, False]
sage: bg.private_key(19, 23)
(19, 23, -6, 5)
```

Choose two distinct random Blum primes, compute the Blum-Goldwasser private key corresponding to those two primes, and test that the resulting private key  $(p, q, a, b)$  satisfies  $\gcd(p, q) = ap + bq = 1$ :

```
sage: from sage.crypto.util import random_blum_prime
sage: p = random_blum_prime(10**4, 10**5)
sage: q = random_blum_prime(10**4, 10**5)
sage: while q == p:
.....:     q = random_blum_prime(10**4, 10**5)
sage: p, q, a, b = bg.private_key(p, q)
sage: gcd(p, q) == a*p + b*q == 1
True
```

### `public_key(p, q)`

Return the Blum-Goldwasser public key corresponding to the distinct Blum primes  $p$  and  $q$ .

INPUT:

- $p$  – a Blum prime.
- $q$  – a Blum prime.

OUTPUT:

- The Blum-Goldwasser public key  $n = pq$ .

Both  $p$  and  $q$  must be distinct Blum primes. Let  $p$  be a positive prime. Then  $p$  is a Blum prime if  $p$  is congruent to 3 modulo 4, i.e.  $p \equiv 3 \pmod{4}$ .

EXAMPLES:

Obtain two distinct Blum primes and compute the Blum-Goldwasser public key corresponding to those two Blum primes:

```

sage: from sage.crypto.public_key.blum_goldwasser import BlumGoldwasser
sage: from sage.crypto.util import is_blum_prime
sage: bg = BlumGoldwasser()
sage: P = primes_first_n(10); P
[2, 3, 5, 7, 11, 13, 17, 19, 23, 29]
sage: [is_blum_prime(_) for _ in P]
[False, True, False, True, True, False, False, True, True, False]
sage: bg.public_key(3, 7)
21

```

Choose two distinct random Blum primes, compute the Blum-Goldwasser public key corresponding to those two primes, and test that the public key factorizes into Blum primes:

```

sage: from sage.crypto.util import random_blum_prime
sage: p = random_blum_prime(10**4, 10**5)
sage: q = random_blum_prime(10**4, 10**5)
sage: while q == p:
....:     q = random_blum_prime(10**4, 10**5)
...
sage: n = bg.public_key(p, q)
sage: f = factor(n)
sage: is_blum_prime(f[0][0]); is_blum_prime(f[1][0])
True
True
sage: p * q == f[0][0] * f[1][0]
True

```

**random\_key**(*lbound*, *ubound*, *ntries*=100)

Return a pair of random public and private keys.

INPUT:

- *lbound* – positive integer; the lower bound on how small each random Blum prime  $p$  and  $q$  can be. So we have  $0 < \text{lower\_bound} \leq p, q \leq \text{upper\_bound}$ . The lower bound must be distinct from the upper bound.
- *ubound* – positive integer; the upper bound on how large each random Blum prime  $p$  and  $q$  can be. So we have  $0 < \text{lower\_bound} \leq p, q \leq \text{upper\_bound}$ . The lower bound must be distinct from the upper bound.
- *ntries* – (default: 100) the number of attempts to generate a random public/private key pair. If *ntries* is a positive integer, then perform that many attempts at generating a random public/private key pair.

OUTPUT:

- A random public key and its corresponding private key. Each randomly chosen  $p$  and  $q$  are guaranteed to be Blum primes. The public key is  $n = pq$ , and the private key is  $(p, q, a, b)$  where  $\gcd(p, q) = ap + bq = 1$ .

ALGORITHM:

The key generation algorithm is described in Algorithm 8.55, page 308 of [MvOV1996]. The algorithm works as follows:

1. Let  $p$  and  $q$  be distinct large random primes, each congruent to 3 modulo 4. That is,  $p$  and  $q$  are Blum primes.

2. Let  $n = pq$  be the product of  $p$  and  $q$ .
3. Use the extended Euclidean algorithm to compute integers  $a$  and  $b$  such that  $\gcd(p, q) = ap + bq = 1$ .
4. The public key is  $n$  and the corresponding private key is  $(p, q, a, b)$ .

---

**Note:** Beware that there might not be any primes between the lower and upper bounds. So make sure that these two bounds are “sufficiently” far apart from each other for there to be primes congruent to 3 modulo 4. In particular, there should be at least two distinct primes within these bounds, each prime being congruent to 3 modulo 4.

---

EXAMPLES:

Choosing a random pair of public and private keys. We then test to see if they satisfy the requirements of the Blum-Goldwasser scheme:

```
sage: from sage.crypto.public_key.blum_goldwasser import BlumGoldwasser
sage: from sage.crypto.util import is_blum_prime
sage: bg = BlumGoldwasser()
sage: pubkey, prikey = bg.random_key(10**4, 10**5)
sage: p, q, a, b = prikey
sage: is_blum_prime(p); is_blum_prime(q)
True
True
sage: p == q
False
sage: pubkey == p*q
True
sage: gcd(p, q) == a*p + b*q == 1
True
```

## STREAM CRYPTOSYSTEMS

**class** sage.crypto.stream.LFSRCryptosystem(*field=None*)

Bases: *SymmetricKeyCryptosystem*

Linear feedback shift register cryptosystem class

**encoding**(*M*)

**class** sage.crypto.stream.ShrinkingGeneratorCryptosystem(*field=None*)

Bases: *SymmetricKeyCryptosystem*

Shrinking generator cryptosystem class

**encoding**(*M*)

sage.crypto.stream.blum\_blum\_shub(*length, seed=None, p=None, q=None, lbound=None, ubound=None, ntries=100*)

The Blum-Blum-Shub (BBS) pseudorandom bit generator.

See the original paper by Blum, Blum and Shub [BBS1986]. The BBS algorithm is also discussed in section 5.5.2 of [MvOV1996].

INPUT:

- **length** – positive integer; the number of bits in the output pseudorandom bit sequence.
- **seed** – (default: `None`) if *p* and *q* are Blum primes, then **seed** is a quadratic residue in the multiplicative group  $(\mathbf{Z}/n\mathbf{Z})^*$  where  $n = pq$ . If **seed**=`None`, then the function would generate its own random quadratic residue in  $(\mathbf{Z}/n\mathbf{Z})^*$ . If you provide a value for **seed**, then it is your responsibility to ensure that the seed is a quadratic residue in the multiplicative group  $(\mathbf{Z}/n\mathbf{Z})^*$ .
- **p** – (default: `None`) a large positive prime congruent to 3 modulo 4. Both *p* and *q* must be distinct. If **p**=`None`, then a value for *p* will be generated, where  $0 < \text{lower\_bound} \leq p \leq \text{upper\_bound}$ .
- **q** – (default: `None`) a large positive prime congruence to 3 modulo 4. Both *p* and *q* must be distinct. If **q**=`None`, then a value for *q* will be generated, where  $0 < \text{lower\_bound} \leq q \leq \text{upper\_bound}$ .
- **lbound** – (positive integer, default: `None`) the lower bound on how small each random primes *p* and *q* can be. So we have  $0 < \text{lbound} \leq p, q \leq \text{ubound}$ . The lower bound must be distinct from the upper bound.
- **ubound** – (positive integer, default: `None`) the upper bound on how large each random primes *p* and *q* can be. So we have  $0 < \text{lbound} \leq p, q \leq \text{ubound}$ . The lower bound must be distinct from the upper bound.
- **ntries** – (default: `100`) the number of attempts to generate a random Blum prime. If **ntries** is a positive integer, then perform that many attempts at generating a random Blum prime. This might or might not result in a Blum prime.

OUTPUT:

- A pseudorandom bit sequence whose length is specified by `length`.

Here is a common use case for this function. If you want this function to use pre-computed values for  $p$  and  $q$ , you should pass those pre-computed values to this function. In that case, you only need to specify values for `length`, `p` and `q`, and you do not need to worry about doing anything with the parameters `lbound` and `ubound`. The pre-computed values  $p$  and  $q$  must be Blum primes. It is your responsibility to check that both  $p$  and  $q$  are Blum primes.

Here is another common use case. If you want the function to generate its own values for  $p$  and  $q$ , you must specify the lower and upper bounds within which these two primes must lie. In that case, you must specify values for `length`, `lbound` and `ubound`, and you do not need to worry about values for the parameters `p` and `q`. The parameter `ntries` is only relevant when you want this function to generate `p` and `q`.

---

**Note:** Beware that there might not be any primes between the lower and upper bounds. So make sure that these two bounds are “sufficiently” far apart from each other for there to be primes congruent to 3 modulo 4. In particular, there should be at least two distinct primes within these bounds, each prime being congruent to 3 modulo 4. This function uses the function `random_blum_prime()` to generate random primes that are congruent to 3 modulo 4.

---

ALGORITHM:

The BBS algorithm as described below is adapted from the presentation in Algorithm 5.40, page 186 of [MvOV1996].

1. Let  $L$  be the desired number of bits in the output bit sequence. That is,  $L$  is the desired length of the bit string.
2. Let  $p$  and  $q$  be two large distinct primes, each congruent to 3 modulo 4.
3. Let  $n = pq$  be the product of  $p$  and  $q$ .
4. Select a random seed value  $s \in (\mathbf{Z}/n\mathbf{Z})^*$ , where  $(\mathbf{Z}/n\mathbf{Z})^*$  is the multiplicative group of  $\mathbf{Z}/n\mathbf{Z}$ .
5. Let  $x_0 = s^2 \bmod n$ .
6. For  $i$  from 1 to  $L$ , do
  1. Let  $x_i = x_{i-1}^2 \bmod n$ .
  2. Let  $z_i$  be the least significant bit of  $x_i$ .
7. The output pseudorandom bit sequence is  $z_1, z_2, \dots, z_L$ .

EXAMPLES:

A BBS pseudorandom bit sequence with a specified seed:

```
sage: from sage.crypto.stream import blum_blum_shub
sage: blum_blum_shub(length=6, seed=3, p=11, q=19)
110000
```

You could specify the length of the bit string, with given values for `p` and `q`:

```
sage: blum_blum_shub(length=6, p=11, q=19) # random
001011
```

Or you could specify the length of the bit string, with given values for the lower and upper bounds:

```
sage: blum_blum_shub(length=6, lbound=10**4, ubound=10**5) # random
110111
```

Under some reasonable hypotheses, Blum-Blum-Shub [BBS1982] sketch a proof that the period of the BBS stream cipher is equal to  $\lambda(\lambda(n))$ , where  $\lambda(n)$  is the Carmichael function of  $n$ . This is verified below in a few examples by using the function `lfsr_connection_polynomial()` (written by Tim Brock) which computes the connection polynomial of a linear feedback shift register sequence. The degree of that polynomial is the period.

```
sage: from sage.crypto.stream import blum_blum_shub
sage: from sage.arith.misc import carmichael_lambda
sage: carmichael_lambda(carmichael_lambda(7*11))
4
sage: s = [GF(2)(int(str(x))) for x in blum_blum_shub(60, p=7, q=11, seed=13)]
sage: lfsr_connection_polynomial(s)
x^3 + x^2 + x + 1
sage: carmichael_lambda(carmichael_lambda(11*23))
20
sage: s = [GF(2)(int(str(x))) for x in blum_blum_shub(60, p=11, q=23, seed=13)]
sage: lfsr_connection_polynomial(s)
x^19 + x^18 + x^17 + x^16 + x^15 + x^14 + x^13 + x^12 + x^11 + x^10 + x^9 + x^8 + x^
↪7 + x^6 + x^5 + x^4 + x^3 + x^2 + x + 1
```

## STREAM CIPHERS

**class** sage.crypto.stream\_cipher.LFSRCipher(*parent, poly, IS*)

Bases: *SymmetricKeyCipher*

Create a linear feedback shift register (LFSR) cipher.

INPUT:

- *parent* - parent
- *poly* - connection polynomial
- *IS* - initial state

EXAMPLES:

```
sage: FF = FiniteField(2)
sage: P.<x> = PolynomialRing(FF)
sage: E = LFSRCryptosystem(FF)
sage: E
LFSR cryptosystem over Finite Field of size 2
sage: IS = [ FF(a) for a in [0,1,1,1,0,1,1] ]
sage: g = x^7 + x + 1
sage: e = E((g,IS))
sage: B = BinaryStrings()
sage: m = B.encoding("THECATINTHEHAT")
sage: e(m)
001000110111101011101010101000110000000011010001010101110000101111001001000001111110010010001100110
sage: FF = FiniteField(2)
sage: P.<x> = PolynomialRing(FF)
sage: LFSR = LFSRCryptosystem(FF)
sage: e = LFSR((x^2+x+1,[FF(0),FF(1)]))
sage: B = e.domain()
sage: m = B.encoding("The cat in the hat.")
sage: e(m)
00111001110111101011111001001101110101011011101000011001100101101011001000000011100101101010111100
sage: m == e(e(m))
True
```

**connection\_polynomial()**

The connection polynomial defining the LFSR of the cipher.

EXAMPLES:

```

sage: k = GF(2)
sage: P.<x> = PolynomialRing( k )
sage: LFSR = LFSRCryptosystem( k )
sage: e = LFSR((x^2+x+1,[k(0), k(1)]))
sage: e.connection_polynomial()
x^2 + x + 1

```

### `initial_state()`

The initial state of the LFSR cipher.

EXAMPLES:

```

sage: k = GF(2)
sage: P.<x> = PolynomialRing( k )
sage: LFSR = LFSRCryptosystem( k )
sage: e = LFSR((x^2+x+1,[k(0), k(1)]))
sage: e.initial_state()
[0, 1]

```

### `class sage.crypto.stream_cipher.ShrinkingGeneratorCipher(parent, e1, e2)`

Bases: *SymmetricKeyCipher*

Create a shrinking generator cipher.

INPUT:

- parent - parent
- poly - connection polynomial
- IS - initial state

EXAMPLES:

```

sage: FF = FiniteField(2)
sage: P.<x> = PolynomialRing(FF)
sage: LFSR = LFSRCryptosystem(FF)
sage: IS_1 = [ FF(a) for a in [0,1,0,1,0,0,0] ]
sage: e1 = LFSR((x^7 + x + 1,IS_1))
sage: IS_2 = [ FF(a) for a in [0,0,1,0,0,0,1,0,1] ]
sage: e2 = LFSR((x^9 + x^3 + 1,IS_2))
sage: E = ShrinkingGeneratorCryptosystem()
sage: e = E((e1,e2))
sage: e
Shrinking generator cipher on Free binary string monoid

```

### `decimating_cipher()`

The LFSR cipher generating the decimating key stream.

EXAMPLES:

```

sage: FF = FiniteField(2)
sage: P.<x> = PolynomialRing(FF)
sage: LFSR = LFSRCryptosystem(FF)
sage: IS_1 = [ FF(a) for a in [0,1,0,1,0,0,0] ]
sage: e1 = LFSR((x^7 + x + 1,IS_1))

```

(continues on next page)

(continued from previous page)

```
sage: IS_2 = [ FF(a) for a in [0,0,1,0,0,0,1,0,1] ]
sage: e2 = LFSR((x^9 + x^3 + 1, IS_2))
sage: E = ShrinkingGeneratorCryptosystem()
sage: e = E((e1, e2))
sage: e.decimating_cipher()
LFSR cipher on Free binary string monoid
```

**keystream\_cipher()**

The LFSR cipher generating the output key stream.

EXAMPLES:

```
sage: FF = FiniteField(2)
sage: P.<x> = PolynomialRing(FF)
sage: LFSR = LFSRCryptosystem(FF)
sage: IS_1 = [ FF(a) for a in [0,1,0,1,0,0,0] ]
sage: e1 = LFSR((x^7 + x + 1, IS_1))
sage: IS_2 = [ FF(a) for a in [0,0,1,0,0,0,1,0,1] ]
sage: e2 = LFSR((x^9 + x^3 + 1, IS_2))
sage: E = ShrinkingGeneratorCryptosystem()
sage: e = E((e1, e2))
sage: e.keystream_cipher()
LFSR cipher on Free binary string monoid
```

## LINEAR FEEDBACK SHIFT REGISTER (LFSR) SEQUENCE COMMANDS

Stream ciphers have been used for a long time as a source of pseudo-random number generators.

S. Golomb [Go1967] gives a list of three statistical properties that a sequence of numbers  $\mathbf{a} = \{a_n\}_{n=1}^{\infty}$ ,  $a_n \in \{0, 1\}$  should display to be considered “random”. Define the autocorrelation of  $\mathbf{a}$  to be

$$C(k) = C(k, \mathbf{a}) = \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{n=1}^N (-1)^{a_n + a_{n+k}}.$$

In the case where  $\mathbf{a}$  is periodic with period  $P$ , then this reduces to

$$C(k) = \frac{1}{P} \sum_{n=1}^P (-1)^{a_n + a_{n+k}}.$$

Assume  $\mathbf{a}$  is periodic with period  $P$ .

- balance:  $|\sum_{n=1}^P (-1)^{a_n}| \leq 1$ .
- low autocorrelation:

$$C(k) = \begin{cases} 1, & k = 0, \\ \epsilon, & k \neq 0. \end{cases}$$

(For sequences satisfying these first two properties, it is known that  $\epsilon = -1/P$  must hold.)

- proportional runs property: In each period, half the runs have length 1, one-fourth have length 2, etc. Moreover, there are as many runs of 1’s as there are of 0’s.

A general feedback shift register is a map  $f : \mathbf{F}_q^d \rightarrow \mathbf{F}_q^d$  of the form

$$\begin{aligned} f(x_0, \dots, x_{n-1}) &= (x_1, x_2, \dots, x_n), \\ x_n &= C(x_0, \dots, x_{n-1}), \end{aligned}$$

where  $C : \mathbf{F}_q^d \rightarrow \mathbf{F}_q$  is a given function. When  $C$  is of the form

$$C(x_0, \dots, x_{n-1}) = a_0 x_0 + \dots + a_{n-1} x_{n-1},$$

for some given constants  $a_i \in \mathbf{F}_q$ , the map is called a linear feedback shift register (LFSR).

Example of an LFSR: Let

$$f(x) = a_0 + a_1 x + \dots + a_n x^n + \dots,$$

$$g(x) = b_0 + b_1 x + \dots + b_n x^n + \dots,$$

be given polynomials in  $\mathbf{F}_2[x]$  and let

$$h(x) = \frac{f(x)}{g(x)} = c_0 + c_1x + \dots + c_nx^n + \dots$$

We can compute a recursion formula which allows us to rapidly compute the coefficients of  $h(x)$  (take  $f(x) = 1$ ):

$$c_n = \sum_{i=1}^n \frac{-b_i}{b_0} c_{n-i}.$$

The coefficients of  $h(x)$  can, under certain conditions on  $f(x)$  and  $g(x)$ , be considered “random” from certain statistical points of view.

Example: For instance, if

$$f(x) = 1, \quad g(x) = x^4 + x + 1,$$

then

$$h(x) = 1 + x + x^2 + x^3 + x^5 + x^7 + x^8 + \dots$$

The coefficients of  $h$  are

$$\begin{aligned} &1, 1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0, 1, \\ &1, 1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0, 1, \dots \end{aligned}$$

The sequence of 0, 1’s is periodic with period  $P = 2^4 - 1 = 15$  and satisfies Golomb’s three randomness conditions. However, this sequence of period 15 can be “cracked” (i.e., a procedure to reproduce  $g(x)$ ) by knowing only 8 terms! This is the function of the Berlekamp-Massey algorithm [Mas1969], implemented in `berlekamp_massey.py`.

AUTHORS:

- David Joyner (2005-11-24): initial creation.
- Timothy Brock (2005-11): added `lfsr_sequence` with code modified from Python Cookbook, <http://aspn.activestate.com/ASPN/Python/Cookbook/>
- Timothy Brock (2006-04-17): added `lfsr_autocorrelation` and `lfsr_connection_polynomial`.

`sage.crypto.lfsr.lfsr_autocorrelation(L, p, k)`

INPUT:

- $L$  – a periodic sequence of elements of  $\mathbb{Z}\mathbb{Z}$  or  $\text{GF}(2)$ ; must have length  $p$
- $p$  – the period of  $L$
- $k$  – an integer between 0 and  $p$

OUTPUT: autocorrelation sequence of  $L$

EXAMPLES:

```
sage: F = GF(2)
sage: o = F(0)
sage: l = F(1)
sage: key = [1,o,o,l]; fill = [1,1,o,l]; n = 20
sage: s = lfsr_sequence(key,fill,n)
sage: lfsr_autocorrelation(s,15,7)
4/15
sage: lfsr_autocorrelation(s,int(15),7)
4/15
```

`sage.crypto.lfsr.lfsr_connection_polynomial(s)`

INPUT:

- $s$  – a sequence of elements of a finite field of even length

OUTPUT:

- $C(x)$  – the connection polynomial of the minimal LFSR.

This implements the algorithm in section 3 of J. L. Massey's article [Mas1969].

EXAMPLES:

```
sage: F = GF(2)
sage: F
Finite Field of size 2
sage: o = F(0); l = F(1)
sage: key = [1,o,o,l]; fill = [1,1,o,l]; n = 20
sage: s = lfsr_sequence(key,fill,n); s
[1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0, 1, 1, 1, 1, 0, 1, 0]
sage: lfsr_connection_polynomial(s)
x^4 + x + 1
sage: from sage.matrix.berlekamp_massey import berlekamp_massey
sage: berlekamp_massey(s)
x^4 + x^3 + 1
```

Notice that `berlekamp_massey` returns the reverse of the connection polynomial (and is potentially much faster than this implementation).

`sage.crypto.lfsr.lfsr_sequence(key, fill, n)`

Create an LFSR sequence.

INPUT:

- $key$  – a list of finite field elements,  $[c_0, c_1, \dots, c_k]$
- $fill$  – the list of the initial terms of the LFSR sequence,  $[x_0, x_1, \dots, x_k]$
- $n$  – number of terms of the sequence that the function returns

OUTPUT:

The LFSR sequence defined by  $x_{n+1} = c_k x_n + \dots + c_0 x_{n-k}$  for  $n \geq k$ .

EXAMPLES:

```
sage: F = GF(2); l = F(1); o = F(0)
sage: F = GF(2); S = LaurentSeriesRing(F, 'x'); x = S.gen()
sage: fill = [1,1,o,l]; key = [1,o,o,l]; n = 20
sage: L = lfsr_sequence(key,fill,20); L
[1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0, 1, 1, 1, 1, 0, 1, 0]
sage: from sage.matrix.berlekamp_massey import berlekamp_massey
sage: g = berlekamp_massey(L); g
x^4 + x^3 + 1
sage: (1)/(g.reverse()+O(x^20))
1 + x + x^2 + x^3 + x^5 + x^7 + x^8 + x^11 + x^15 + x^16 + x^17 + x^18 + O(x^20)
sage: (1+x^2)/(g.reverse()+O(x^20))
1 + x + x^4 + x^8 + x^9 + x^10 + x^11 + x^13 + x^15 + x^16 + x^19 + O(x^20)
sage: (1+x^2+x^3)/(g.reverse()+O(x^20))
1 + x + x^3 + x^5 + x^6 + x^9 + x^13 + x^14 + x^15 + x^16 + x^18 + O(x^20)
```

(continues on next page)

(continued from previous page)

```
sage: fill = [1,1,0,1]; key = [1,0,0,0]; n = 20
sage: L = lfsr_sequence(key,fill,20); L
[1, 1, 0, 1, 1, 1, 0, 1, 1, 1, 0, 1, 1, 1, 0, 1, 1, 1, 0, 1]
sage: g = berlekamp_massey(L); g
x^4 + 1
sage: (1+x)/(g.reverse()+O(x^20))
1 + x + x^4 + x^5 + x^8 + x^9 + x^12 + x^13 + x^16 + x^17 + O(x^20)
sage: (1+x+x^3)/(g.reverse()+O(x^20))
1 + x + x^3 + x^4 + x^5 + x^7 + x^8 + x^9 + x^11 + x^12 + x^13 + x^15 + x^16 + x^17
↪+ x^19 + O(x^20)
```

## UTILITY FUNCTIONS FOR CRYPTOGRAPHY

Miscellaneous utility functions for cryptographic purposes.

AUTHORS:

- Minh Van Nguyen (2009-12): initial version with the following functions: `ascii_integer`, `ascii_to_bin`, `bin_to_ascii`, `has_blum_prime`, `is_blum_prime`, `least_significant_bits`, `random_blum_prime`.

`sage.crypto.util.ascii_integer(B)`

Return the ASCII integer corresponding to the binary string B.

INPUT:

- B – a non-empty binary string or a non-empty list of bits. The number of bits in B must be 8.

OUTPUT:

- The ASCII integer corresponding to the 8-bit block B.

EXAMPLES:

The ASCII integers of some binary strings:

```
sage: from sage.crypto.util import ascii_integer
sage: bin = BinaryStrings()
sage: B = bin.encoding("A"); B
01000001
sage: ascii_integer(B)
65
sage: B = bin.encoding("C"); list(B)
[0, 1, 0, 0, 0, 0, 1, 1]
sage: ascii_integer(list(B))
67
sage: ascii_integer("01000100")
68
sage: ascii_integer([0, 1, 0, 0, 0, 1, 0, 1])
69
```

`sage.crypto.util.ascii_to_bin(A)`

Return the binary representation of the ASCII string A.

INPUT:

- A – a string or list of ASCII characters.

OUTPUT:

- The binary representation of A.

ALGORITHM:

Let  $A = a_0a_1 \cdots a_{n-1}$  be an ASCII string, where each  $a_i$  is an ASCII character. Let  $c_i$  be the ASCII integer corresponding to  $a_i$  and let  $b_i$  be the binary representation of  $c_i$ . The binary representation  $B$  of  $A$  is  $B = b_0b_1 \cdots b_{n-1}$ .

EXAMPLES:

The binary representation of some ASCII strings:

```
sage: from sage.crypto.util import ascii_to_bin
sage: ascii_to_bin("A")
01000001
sage: ascii_to_bin("Abc123")
010000010110001001100011001100010011001000110011
```

The empty string is different from the string with one space character. For the empty string and the empty list, this function returns the same result:

```
sage: from sage.crypto.util import ascii_to_bin
sage: ascii_to_bin("")

sage: ascii_to_bin(" ")
00100000
sage: ascii_to_bin([])
```

This function also accepts a list of ASCII characters. You can also pass in a list of strings:

```
sage: from sage.crypto.util import ascii_to_bin
sage: ascii_to_bin(["A", "b", "c", "1", "2", "3"])
010000010110001001100011001100010011001000110011
sage: ascii_to_bin(["A", "bc", "1", "23"])
010000010110001001100011001100010011001000110011
```

`sage.crypto.util.bin_to_ascii(B)`

Return the ASCII representation of the binary string B.

INPUT:

- B – a non-empty binary string or a non-empty list of bits. The number of bits in B must be a multiple of 8.

OUTPUT:

- The ASCII string corresponding to B.

ALGORITHM:

Consider a block of bits  $B = b_0b_1 \cdots b_{n-1}$  where each sub-block  $b_i$  is a binary string of length 8. Then the total number of bits is a multiple of 8 and is given by  $8n$ . Let  $c_i$  be the integer representation of  $b_i$ . We can consider  $c_i$  as the integer representation of an ASCII character. Then the ASCII representation  $A$  of  $B$  is  $A = a_0a_1 \cdots a_{n-1}$ .

EXAMPLES:

Convert some ASCII strings to their binary representations and recover the ASCII strings from the binary representations:

```
sage: from sage.crypto.util import ascii_to_bin
sage: from sage.crypto.util import bin_to_ascii
sage: A = "Abc"
```

(continues on next page)

(continued from previous page)

```
sage: B = ascii_to_bin(A); B
010000010110001001100011
sage: bin_to_ascii(B)
'Abc'
sage: bin_to_ascii(B) == A
True
```

```
sage: A = "123 \" #"
sage: B = ascii_to_bin(A); B
00110001001100100011001100100000001000100010000000100011
sage: bin_to_ascii(B)
'123 " #'
sage: bin_to_ascii(B) == A
True
```

This function also accepts strings and lists of bits:

```
sage: from sage.crypto.util import bin_to_ascii
sage: bin_to_ascii("010000010110001001100011")
'Abc'
sage: bin_to_ascii([0, 1, 0, 0, 0, 0, 0, 1])
'A'
```

`sage.crypto.util.has_blum_prime(lbound, ubound)`

Determine whether or not there is a Blum prime within the specified closed interval.

INPUT:

- `lbound` – positive integer; the lower bound on how small a Blum prime can be. The lower bound must be distinct from the upper bound.
- `ubound` – positive integer; the upper bound on how large a Blum prime can be. The lower bound must be distinct from the upper bound.

OUTPUT:

- True if there is a Blum prime  $p$  such that  $lbound \leq p \leq ubound$ . False otherwise.

ALGORITHM:

Let  $L$  and  $U$  be distinct positive integers. Let  $P$  be the set of all odd primes  $p$  such that  $L \leq p \leq U$ . Our main focus is on Blum primes, i.e. odd primes that are congruent to 3 modulo 4, so we assume that the lower bound  $L > 2$ . The closed interval  $[L, U]$  has a Blum prime if and only if the set  $P$  has a Blum prime.

EXAMPLES:

Testing for the presence of Blum primes within some closed intervals. The interval  $[4, 100]$  has a Blum prime, the smallest such prime being 7. The interval  $[24, 28]$  has no primes, hence no Blum primes.

```
sage: from sage.crypto.util import has_blum_prime
sage: from sage.crypto.util import is_blum_prime
sage: has_blum_prime(4, 100)
True
sage: for n in range(4, 100):
.....:     if is_blum_prime(n):
.....:         print(n)
```

(continues on next page)

(continued from previous page)

```

.....:      break
7
sage: has_blum_prime(24, 28)
False

```

`sage.crypto.util.is_blum_prime(n)`

Determine whether or not *n* is a Blum prime.

INPUT:

- *n* a positive prime.

OUTPUT:

- True if *n* is a Blum prime; False otherwise.

Let *n* be a positive prime. Then *n* is a Blum prime if *n* is congruent to 3 modulo 4, i.e.  $n \equiv 3 \pmod{4}$ .

EXAMPLES:

Testing some integers to see if they are Blum primes:

```

sage: from sage.crypto.util import is_blum_prime
sage: from sage.crypto.util import random_blum_prime
sage: is_blum_prime(101)
False
sage: is_blum_prime(7)
True
sage: p = random_blum_prime(10**3, 10**5)
sage: is_blum_prime(p)
True

```

`sage.crypto.util.least_significant_bits(n, k)`

Return the *k* least significant bits of *n*.

INPUT:

- *n* – an integer.
- *k* – a positive integer.

OUTPUT:

- The *k* least significant bits of the integer *n*. If *k*=1, then return the parity bit of the integer *n*. Let *b* be the binary representation of *n*, where *m* is the length of the binary string *b*. If  $k \geq m$ , then return the binary representation of *n*.

EXAMPLES:

Obtain the parity bits of some integers:

```

sage: from sage.crypto.util import least_significant_bits
sage: least_significant_bits(0, 1)
[0]
sage: least_significant_bits(2, 1)
[0]
sage: least_significant_bits(3, 1)
[1]
sage: least_significant_bits(-2, 1)

```

(continues on next page)

(continued from previous page)

```
[0]
sage: least_significant_bits(-3, 1)
[1]
```

Obtain the 4 least significant bits of some integers:

```
sage: least_significant_bits(101, 4)
[0, 1, 0, 1]
sage: least_significant_bits(-101, 4)
[0, 1, 0, 1]
sage: least_significant_bits(124, 4)
[1, 1, 0, 0]
sage: least_significant_bits(-124, 4)
[1, 1, 0, 0]
```

The binary representation of 123:

```
sage: n = 123; b = n.binary(); b
'1111011'
sage: least_significant_bits(n, len(b))
[1, 1, 1, 1, 0, 1, 1]
```

`sage.crypto.util.random_blum_prime(lbound, ubound, ntries=100)`

A random Blum prime within the specified bounds.

Let  $p$  be a positive prime. Then  $p$  is a Blum prime if  $p$  is congruent to 3 modulo 4, i.e.  $p \equiv 3 \pmod{4}$ .

INPUT:

- `lbound` – positive integer; the lower bound on how small a random Blum prime  $p$  can be. So we have  $0 < \text{lbound} \leq p \leq \text{ubound}$ . The lower bound must be distinct from the upper bound.
- `ubound` – positive integer; the upper bound on how large a random Blum prime  $p$  can be. So we have  $0 < \text{lbound} \leq p \leq \text{ubound}$ . The lower bound must be distinct from the upper bound.
- `ntries` – (default: 100) the number of attempts to generate a random Blum prime. If `ntries` is a positive integer, then perform that many attempts at generating a random Blum prime. This might or might not result in a Blum prime.

OUTPUT:

- A random Blum prime within the specified lower and upper bounds.

---

**Note:** Beware that there might not be any primes between the lower and upper bounds. So make sure that these two bounds are “sufficiently” far apart from each other for there to be primes congruent to 3 modulo 4. In particular, there should be at least two distinct Blum primes within the specified bounds.

---

EXAMPLES:

Choose a random prime and check that it is a Blum prime:

```
sage: from sage.crypto.util import random_blum_prime
sage: p = random_blum_prime(10**4, 10**5)
sage: is_prime(p)
True
```

(continues on next page)

(continued from previous page)

```
sage: mod(p, 4) == 3
True
```

## BOOLEAN FUNCTIONS

Those functions are used for example in LFSR based ciphers like the filter generator or the combination generator. This module allows to study properties linked to spectral analysis, and also algebraic immunity.

EXAMPLES:

```
sage: R.<x> = GF(2^8, 'a') []
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction( x^254 ) # the Boolean function Tr(x^254)
sage: B
Boolean function with 8 variables
sage: B.nonlinearity()
112
sage: B.algebraic_immunity()
4
```

AUTHOR:

- Rusydi H. Makarim (2016-10-13): add functions related to linear structures
- Rusydi H. Makarim (2016-07-09): add is\_plateaued()
- Yann Laigle-Chapuy (2010-02-26): add basic arithmetic
- Yann Laigle-Chapuy (2009-08-28): first implementation

**class** sage.crypto.boolean\_function.**BooleanFunction**

Bases: SageObject

This module implements Boolean functions represented as a truth table.

We can construct a Boolean Function from either:

- an integer - the result is the zero function with  $x$  variables;
- a list - it is expected to be the truth table of the result. Therefore it must be of length a power of 2, and its elements are interpreted as Booleans;
- a string - representing the truth table in hexadecimal;
- a Boolean polynomial - the result is the corresponding Boolean function;
- a polynomial  $P$  over an extension of  $GF(2)$  - the result is the Boolean function with truth table (  $Tr(P(x))$  for  $x$  in  $GF(2^k)$  )

EXAMPLES:

from the number of variables:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: BooleanFunction(5)
Boolean function with 5 variables
```

from a truth table:

```
sage: BooleanFunction([1,0,0,1])
Boolean function with 2 variables
```

note that elements can be of different types:

```
sage: B = BooleanFunction([False, sqrt(2)])
sage: B
Boolean function with 1 variable
sage: [b for b in B]
[False, True]
```

from a string:

```
sage: BooleanFunction("111e")
Boolean function with 4 variables
```

from a `sage.rings.polynomial.pbori.BooleanPolynomial`:

```
sage: R.<x,y,z> = BooleanPolynomialRing(3)
sage: P = x*y
sage: BooleanFunction( P )
Boolean function with 3 variables
```

from a polynomial over a binary field:

```
sage: R.<x> = GF(2^8, 'a')[ ]
sage: B = BooleanFunction( x^7 )
sage: B
Boolean function with 8 variables
```

two failure cases:

```
sage: BooleanFunction(sqrt(2))
Traceback (most recent call last):
...
TypeError: unable to init the Boolean function

sage: BooleanFunction([1, 0, 1])
Traceback (most recent call last):
...
ValueError: the length of the truth table must be a power of 2
```

**absolut\_indicator**(\*args, \*\*kws)

Deprecated: Use `absolute_indicator()` instead. See [github issue #28001](#) for details.

**absolute\_autocorrelation**()

Return the absolute autocorrelation of the function.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction("7969817CC5893BA6AC326E47619F5AD0")
sage: sorted(B.absolute_autocorrelation().items())
[(0, 33), (8, 58), (16, 28), (24, 6), (32, 2), (128, 1)]
```

**absolute\_indicator()**

Return the absolute indicator of the function.

The absolute indicator is defined as the maximal absolute value of the autocorrelation.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction("7969817CC5893BA6AC326E47619F5AD0")
sage: B.absolute_indicator()
32
```

The old method's name contained a typo, it is deprecated:

```
sage: B.absolut_indicator()
doctest:warning
...
DeprecationWarning: absolut_indicator is deprecated. Please use absolute_
↪indicator instead.
See https://github.com/sagemath/sage/issues/28001 for details.
32
```

**absolute\_walsh\_spectrum()**

Return the absolute Walsh spectrum fo the function.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction("7969817CC5893BA6AC326E47619F5AD0")
sage: sorted(B.absolute_walsh_spectrum().items())
[(0, 64), (16, 64)]

sage: B = BooleanFunction("0113077C165E76A8")
sage: B.absolute_walsh_spectrum()
{8: 64}
```

**algebraic\_degree()**

Return the algebraic degree of this Boolean function.

The algebraic degree of a Boolean function is defined as the degree of its algebraic normal form. Note that the degree of the constant zero function is defined to be equal to -1.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B.<x0, x1, x2, x3> = BooleanPolynomialRing()
sage: f = BooleanFunction(x1*x2 + x1*x2*x3 + x1)
sage: f.algebraic_degree()
3
sage: g = BooleanFunction([0, 0])
```

(continues on next page)

(continued from previous page)

```
sage: g.algebraic_degree()
-1
```

**algebraic\_immunity**(*annihilator=False*)

Return the algebraic immunity of the Boolean function.

This is the smallest integer  $i$  such that there exists a non trivial annihilator for *self* or *self*.

INPUT:

- *annihilator* – boolean (default: False); if True, returns also an annihilator of minimal degree

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: R.<x0,x1,x2,x3,x4,x5> = BooleanPolynomialRing(6)
sage: B = BooleanFunction(x0*x1 + x1*x2 + x2*x3 + x3*x4 + x4*x5)
sage: B.algebraic_immunity(annihilator=True)
(2, x0*x1 + x1*x2 + x2*x3 + x3*x4 + x4*x5 + 1)
sage: B[0] +=1
sage: B.algebraic_immunity()
2

sage: R.<x> = GF(2^8,'a')[]
sage: B = BooleanFunction(x^31)
sage: B.algebraic_immunity()
4
```

**algebraic\_normal\_form**()

Return the `sage.rings.polynomial.pbori.BooleanPolynomial` corresponding to the algebraic normal form.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction([0,1,1,0,1,0,1,1])
sage: P = B.algebraic_normal_form()
sage: P
x0*x1*x2 + x0 + x1*x2 + x1 + x2
sage: [ P(*ZZ(i).digits(base=2,padto=3)) for i in range(8) ]
[0, 1, 1, 0, 1, 0, 1, 1]
```

**annihilator**(*d, dim=False*)

Return (if it exists) an annihilator of the boolean function of degree at most  $d$ , that is a Boolean polynomial  $g$  such that

$$f(x)g(x) = 0 \forall x.$$

INPUT:

- $d$  – an integer;
- *dim* – a Boolean (default: False), if True, return also the dimension of the annihilator vector space.

EXAMPLES:

```

sage: from sage.crypto.boolean_function import BooleanFunction
sage: f = BooleanFunction("7969817CC5893BA6AC326E47619F5AD0")
sage: f.annihilator(1) is None
True
sage: g = BooleanFunction( f.annihilator(3) )
sage: set([ fi*g(i) for i,fi in enumerate(f) ])
{0}

```

**autocorrelation()**

Return the autocorrelation of the function, defined by

$$\Delta_f(j) = \sum_{i \in \{0,1\}^n} (-1)^{f(i) \oplus f(i \oplus j)}.$$

EXAMPLES:

```

sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction("03")
sage: B.autocorrelation()
(8, 8, 0, 0, 0, 0, 0, 0)

```

**correlation\_immunity()**

Return the maximum value  $m$  such that the function is correlation immune of order  $m$ .

A Boolean function is said to be correlation immune of order  $m$ , if the output of the function is statistically independent of the combination of any  $m$  of its inputs.

EXAMPLES:

```

sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction("7969817CC5893BA6AC326E47619F5AD0")
sage: B.correlation_immunity()
2

```

**derivative(u)**

Return the derivative in direction of  $u$

INPUT:

- $u$  – either an integer or a tuple/list of  $\mathbb{F}_2$  elements of length equal to the number of variables

The derivative of  $f$  in direction of  $u$  is defined as  $x \mapsto f(x) + f(x + u)$ .

EXAMPLES:

```

sage: from sage.crypto.boolean_function import BooleanFunction
sage: f = BooleanFunction([0,1,0,1,0,1,0,1])
sage: f.derivative(1).algebraic_normal_form()
1
sage: u = [1,0,0]
sage: f.derivative(u).algebraic_normal_form()
1
sage: v = vector(GF(2), u)
sage: f.derivative(u).algebraic_normal_form()
1
sage: f.derivative(8).algebraic_normal_form()

```

(continues on next page)

(continued from previous page)

```

### has\_linear\_structure()

Return True if this function has a linear structure.

An  $n$ -variable Boolean function  $f$  has a linear structure if there exists a nonzero  $a \in \mathbf{F}_2^n$  such that  $f(x \oplus a) \oplus f(x)$  is a constant function.

**See also:**

[is\\_linear\\_structure\(\)](#), [linear\\_structures\(\)](#).

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: f = BooleanFunction([0, 1, 0, 1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0])
sage: f.has_linear_structure()
True
sage: f.autocorrelation()
(16, -16, 0, 0, 0, 0, 0, 0, -16, 16, 0, 0, 0, 0, 0, 0)
sage: g = BooleanFunction([0, 1, 1, 1, 0, 0, 0, 0, 1, 0, 1, 1, 1, 0, 1, 1])
sage: g.has_linear_structure()
False
sage: g.autocorrelation()
(16, 4, 4, 4, 4, -4, -4, -4, -4, 4, -4, -4, -4, 4, -4, -4)
```

### is\_balanced()

Return True if the function takes the value True half of the time.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction(1)
sage: B.is_balanced()
False
sage: B[0] = True
sage: B.is_balanced()
True
```

### is\_bent()

Return True if the function is bent.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction("0113077C165E76A8")
sage: B.is_bent()
True
```

### is\_linear\_structure(val)

Return True if  $val$  is a linear structure of this Boolean function.

INPUT:

- `val` – either an integer or a tuple/list of  $F_2$  elements of length equal to the number of variables

See also:

`has_linear_structure()`, `linear_structures()`.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: f = BooleanFunction([0, 1, 0, 1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0])
sage: f.is_linear_structure(1)
True
sage: l = [1, 0, 0, 1]
sage: f.is_linear_structure(l)
True
sage: v = vector(GF(2), l)
sage: f.is_linear_structure(v)
True
sage: f.is_linear_structure(7)
False
sage: f.is_linear_structure(20) #parameter is out of range
Traceback (most recent call last):
...
IndexError: index out of range
sage: v = vector(GF(3), [1, 0, 1, 1])
sage: f.is_linear_structure(v)
Traceback (most recent call last):
...
TypeError: base ring of input vector must be GF(2)
sage: v = vector(GF(2), [1, 0, 1, 1, 1])
sage: f.is_linear_structure(v)
Traceback (most recent call last):
...
TypeError: input vector must be an element of a vector space with dimension 4
sage: f.is_linear_structure('X') #failure case
Traceback (most recent call last):
...
TypeError: cannot compute is_linear_structure() using parameter X
```

**`is_plateaued()`**

Return True if this function is plateaued, i.e. its Walsh transform takes at most three values 0 and  $\pm\lambda$ , where  $\lambda$  is some positive integer.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: R.<x0, x1, x2, x3> = BooleanPolynomialRing()
sage: f = BooleanFunction(x0*x1 + x2 + x3)
sage: f.walsh_hadamard_transform()
(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 8, 8, 8, -8)
sage: f.is_plateaued()
True
```

**`is_symmetric()`**

Return True if the function is symmetric, i.e. invariant under permutation of its input bits.

Another way to see it is that the output depends only on the Hamming weight of the input.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction(5)
sage: B[3] = 1
sage: B.is_symmetric()
False
sage: V_B = [0, 1, 1, 0, 1, 0]
sage: for i in xrange(32): B[i] = V_B[i].popcount()
sage: B.is_symmetric()
True
```

### **linear\_structures()**

Return all linear structures of this Boolean function as a vector subspace of  $\mathbb{F}_2^n$ .

**See also:**

*is\_linear\_structure(), has\_linear\_structure().*

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: f = BooleanFunction([0, 1, 0, 1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0])
sage: LS = f.linear_structures()
sage: LS.dimension()
2
sage: LS.basis_matrix()
[1 0 0 0]
[0 0 0 1]
sage: LS.list()
[(0, 0, 0, 0), (1, 0, 0, 0), (0, 0, 0, 1), (1, 0, 0, 1)]
```

### **nonlinearity()**

Return the nonlinearity of the function.

This is the distance to the linear functions, or the number of output ones need to change to obtain a linear function.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction(5)
sage: B[1] = B[3] = 1
sage: B.nonlinearity()
2
sage: B = BooleanFunction("0113077C165E76A8")
sage: B.nonlinearity()
28
```

### **nvariables()**

The number of variables of this function.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: BooleanFunction(4).nvariables()
4
```

**resiliency\_order()**

Return the maximum value  $m$  such that the function is resilient of order  $m$ .

A Boolean function is said to be resilient of order  $m$  if it is balanced and correlation immune of order  $m$ .

If the function is not balanced, we return -1.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction(
↪ "077CE5A2F8831A5DF8831A5D077CE5A269966996696996669999665AA5A5A")
sage: B.resiliency_order()
3
```

**sum\_of\_square\_indicator()**

Return the sum of square indicator of the function.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction("7969817CC5893BA6AC326E47619F5AD0")
sage: B.sum_of_square_indicator()
32768
```

**truth\_table(format='bin')**

The truth table of the Boolean function.

INPUT: a string representing the desired format, can be either

- 'bin' (default) : we return a tuple of Boolean values
- 'int' : we return a tuple of 0 or 1 values
- 'hex' : we return a string representing the truth\_table in hexadecimal

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: R.<x,y,z> = BooleanPolynomialRing(3)
sage: B = BooleanFunction( x*y*z + z + y + 1 )
sage: B.truth_table()
(True, True, False, False, False, False, True, False)
sage: B.truth_table(format='int')
(1, 1, 0, 0, 0, 0, 1, 0)
sage: B.truth_table(format='hex')
'43'

sage: BooleanFunction('00ab').truth_table(format='hex')
'00ab'

sage: H = '0abbacadabbacad0'
sage: len(H)
16
sage: T = BooleanFunction(H).truth_table(format='hex')
sage: T == H
True
sage: H = H * 4
```

(continues on next page)

(continued from previous page)

```

sage: T = BooleanFunction(H).truth_table(format='hex')
sage: T == H
True
sage: H = H * 4
sage: T = BooleanFunction(H).truth_table(format='hex')
sage: T == H
True
sage: len(T)
256
sage: B.truth_table(format='oct')
Traceback (most recent call last):
...
ValueError: unknown output format

```

**walsh\_hadamard\_transform()**

Compute the Walsh Hadamard transform  $W$  of the function  $f$ .

$$W(j) = \sum_{i \in \{0,1\}^n} (-1)^{f(i) \oplus i \cdot j}$$

EXAMPLES:

```

sage: from sage.crypto.boolean_function import BooleanFunction
sage: R.<x> = GF(2^3,'a')[]
sage: B = BooleanFunction( x^3 )
sage: B.walsh_hadamard_transform()
(0, -4, 0, 4, 0, 4, 0, 4)

```

**class sage.crypto.boolean\_function.BooleanFunctionIterator**

Bases: object

Iterator through the values of a Boolean function.

EXAMPLES:

```

sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction(3)
sage: type(B.__iter__())
<class 'sage.crypto.boolean_function.BooleanFunctionIterator'>

```

**sage.crypto.boolean\_function.random\_boolean\_function( $n$ )**

Return a random Boolean function with  $n$  variables.

EXAMPLES:

```

sage: from sage.crypto.boolean_function import random_boolean_function
sage: B = random_boolean_function(9)
sage: B.nvariables()
9
sage: while not (210 < B.nonlinearity() < 220):
.....:     B = random_boolean_function(9)

```

**sage.crypto.boolean\_function.unpickle\_BooleanFunction( $bool\_list$ )**

Specific function to unpickle Boolean functions.

EXAMPLES:

```
sage: from sage.crypto.boolean_function import BooleanFunction
sage: B = BooleanFunction([0,1,1,0])
sage: loads(dumps(B)) == B # indirect doctest
True
```

## S-BOXES AND THEIR ALGEBRAIC REPRESENTATIONS

**class** sage.crypto.sbox.SBox

Bases: SageObject

A substitution box or S-box is one of the basic components of symmetric key cryptography. In general, an S-box takes  $m$  input bits and transforms them into  $n$  output bits. This is called an  $m \times n$  S-box and is often implemented as a lookup table. These S-boxes are carefully chosen to resist linear and differential cryptanalysis [He2002].

This module implements an S-box class which allows an algebraic treatment and determine various cryptographic properties.

EXAMPLES:

We consider the S-box of the block cipher PRESENT [BKLPPRSV2007]:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(12,5,6,11,9,0,10,13,3,14,15,8,4,7,1,2); S
(12, 5, 6, 11, 9, 0, 10, 13, 3, 14, 15, 8, 4, 7, 1, 2)
sage: S(1)
5
```

Note that by default bits are interpreted in big endian order. This is not consistent with the rest of Sage, which has a strong bias towards little endian, but is consistent with most cryptographic literature:

```
sage: S([0,0,0,1])
[0, 1, 0, 1]

sage: S = SBox(12,5,6,11,9,0,10,13,3,14,15,8,4,7,1,2, big_endian=False)
sage: S(1)
5
sage: S([0,0,0,1])
[1, 1, 0, 0]
```

Now we construct an SBox object for the 4-bit small scale AES S-Box (cf. *sage.crypto.mq.sr*):

```
sage: sr = mq.SR(1,1,1,4, allow_zero_inversions=True)
sage: S = SBox([sr.sub_byte(e) for e in list(sr.k)])
sage: S
(6, 5, 2, 9, 4, 7, 3, 12, 14, 15, 10, 0, 8, 1, 13, 11)
```

**autocorrelation\_table()**

Return the autocorrelation table corresponding to this S-Box.

for an  $m \times n$  S-Box  $S$ , its autocorrelation table entry at row  $a \in \mathbb{F}_2^m$  and column  $b \in \mathbb{F}_2^n$  (considering their integer representation) is defined as:

$$\sum_{x \in \mathbb{F}_2^m} (-1)^{b \cdot S(x) \oplus b \cdot S(x \oplus a)}.$$

Equivalently, the columns  $b$  of autocorrelation table correspond to the autocorrelation spectrum of component function  $b \cdot S(x)$ .

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: S.autocorrelation_table()
[ 8  8  8  8  8  8  8  8]
[ 8  0  0  0  0  0  0 -8]
[ 8  0 -8  0  0  0  0  0]
[ 8  0  0  0  0 -8  0  0]
[ 8 -8  0  0  0  0  0  0]
[ 8  0  0  0  0  0 -8  0]
[ 8  0  0 -8  0  0  0  0]
[ 8  0  0  0 -8  0  0  0]
```

**boomerang\_connectivity\_table()**

Return the boomerang connectivity table (BCT) for this S-Box.

Boomerang connectivity matrix of an invertible  $m \times m$  S-Box  $S$  is an  $2^m \times 2^m$  matrix with entry at row  $\Delta_i \in \mathbb{F}_2^m$  and column  $\Delta_o \in \mathbb{F}_2^m$  equal to

$$|\{x \in \mathbb{F}_2^m \mid S^{-1}(S(x) \oplus \Delta_o) \oplus S^{-1}(S(x \oplus \Delta_i) \oplus \Delta_o) = \Delta_i\}|.$$

For more results concerning boomerang connectivity matrix, see [CHPSS18]. The algorithm used here is the one from Dunkelman [Du2018].

EXAMPLES:

```
sage: from sage.crypto.sboxes import PRESENT
sage: PRESENT.boomerang_connectivity_table()
[16 16 16 16 16 16 16 16 16 16 16 16 16 16 16]
[16  0  4  4  0 16  4  4  4  4  0  0  4  4  0  0]
[16  0  0  6  0  4  6  0  0  0  2  0  2  2  2  0]
[16  2  0  6  2  4  4  2  0  0  2  2  0  0  0  0]
[16  0  0  0  0  4  2  2  0  6  2  0  6  0  2  0]
[16  2  0  0  2  4  0  0  0  6  2  2  4  2  0  0]
[16  4  2  0  4  0  2  0  2  0  0  4  2  0  4  8]
```

(continues on next page)

(continued from previous page)

```

[16 4 2 0 4 0 2 0 2 0 0 4 2 0 4 8]
[16 4 0 2 4 0 0 2 0 2 0 4 0 2 4 8]
[16 4 2 0 4 0 2 0 2 0 0 4 2 0 4 8]
[16 0 2 2 0 4 0 0 6 0 2 0 0 6 2 0]
[16 2 0 0 2 4 0 0 4 2 2 2 0 6 0 0]
[16 0 6 0 0 4 0 6 2 2 2 0 0 0 2 0]
[16 2 4 2 2 4 0 6 0 0 2 2 0 0 0 0]
[16 0 2 2 0 0 2 2 2 2 0 0 2 2 0 0]
[16 8 0 0 8 0 0 0 0 0 8 0 0 8 16]

```

**boomerang\_uniformity()**

Return the boomerang uniformity

The boomerang uniformity is defined as the highest entry in the boomerang connectivity table, ignoring the first row and column.

EXAMPLES:

```

sage: from sage.crypto.sboxes import AES
sage: AES.boomerang_uniformity()
6

```

**cnf(xi=None, yi=None, format=None)**

Return a representation of this S-Box in conjunctive normal form.

This function examines the truth tables for each output bit of the S-Box and thus has complexity  $n * 2^m$  for an  $m \times n$  S-Box.

INPUT:

- **xi** – (default: 1 . . . m) indices for the input variables
- **yi** – (default: m+1 . . . m+n) indices for the output variables
- **format** – (default: None) output format, see below

FORMATS:

- **None** – return a list of tuples of integers where each tuple represents a clause, the absolute value of an integer represents a variable and the sign of an integer indicates inversion
- **symbolic** – a string that can be parsed by the SymbolicLogic package
- **dimacs** – a string in DIMACS format which is the gold standard for SAT-solver input (cf. <http://www.satlib.org/>)
- **dimacs\_headless** – a string in DIMACS format, but without the header; this is useful for concatenation of outputs

EXAMPLES:

We give a very small example to explain the output format:

```

sage: from sage.crypto.sbox import SBox
sage: S = SBox(1,2,0,3); S
(1, 2, 0, 3)
sage: cnf = S.cnf(); cnf
[(1, 2, -3), (1, 2, 4),
 (1, -2, 3), (1, -2, -4),

```

(continues on next page)

(continued from previous page)

```
(-1, 2, -3), (-1, 2, -4),
(-1, -2, 3), (-1, -2, 4)]
```

This output completely describes the S-Box. For instance, we can check that  $S([0, 1]) \rightarrow [1, 0]$  satisfies every clause if the first input bit corresponds to the index 1 and the last output bit corresponds to the index 3 in the output.

We can convert this representation to the DIMACS format:

```
sage: print(S.cnf(format='dimacs'))
p cnf 4 8
1 2 -3 0
1 2 4 0
1 -2 3 0
1 -2 -4 0
-1 2 -3 0
-1 2 -4 0
-1 -2 3 0
-1 -2 4 0
```

For concatenation we can strip the header:

```
sage: print(S.cnf(format='dimacs_headless'))
1 2 -3 0
1 2 4 0
1 -2 3 0
1 -2 -4 0
-1 2 -3 0
-1 2 -4 0
-1 -2 3 0
-1 -2 4 0
```

This might be helpful in combination with the `xi` and `yi` parameter to assign indices manually:

```
sage: print(S.cnf(xi=[10,20],yi=[30,40], format='dimacs_headless'))
10 20 -30 0
10 20 40 0
10 -20 30 0
10 -20 -40 0
-10 20 -30 0
-10 20 -40 0
-10 -20 30 0
-10 -20 40 0
```

We can also return a string which is parse-able by the SymbolicLogic package:

```
sage: log = SymbolicLogic()
sage: s = log.statement(S.cnf(format='symbolic'))
sage: log.truthtable(s)[1:]
[['False', 'False', 'False', 'False', 'False'],
 ['False', 'False', 'False', 'True', 'False'],
 ['False', 'False', 'True', 'False', 'False'],
 ['False', 'False', 'True', 'True', 'True']]
```

(continues on next page)

(continued from previous page)

```

['False', 'True', 'False', 'False', 'True'],
['False', 'True', 'False', 'True', 'True'],
['False', 'True', 'True', 'False', 'True'],
['False', 'True', 'True', 'True', 'True'],
['True', 'False', 'False', 'False', 'True'],
['True', 'False', 'False', 'True', 'True'],
['True', 'False', 'True', 'False', 'True'],
['True', 'False', 'True', 'True', 'True'],
['True', 'True', 'False', 'False', 'True'],
['True', 'True', 'False', 'True', 'True'],
['True', 'True', 'True', 'False', 'True'],
['True', 'True', 'True', 'True', 'True']

```

This function respects endianness of the S-Box:

```

sage: S = SBox(1,2,0,3, big_endian=False); S
(1, 2, 0, 3)
sage: cnf = S.cnf(); cnf
[(1, 2, -4), (1, 2, 3),
 (-1, 2, 4), (-1, 2, -3),
 (1, -2, -4), (1, -2, -3),
 (-1, -2, 4), (-1, -2, 3)]

```

S-Boxes with  $m \neq n$  also work:

```

sage: o = list(range(8)) + list(range(8)) sage: shuffle(o) sage: S = SBox(o) sage:
S.is_permutation() False
sage: len(S.cnf()) == 3*2^4 True

```

### **component\_function(*b*)**

Return a Boolean function corresponding to the component function  $b \cdot S(x)$ .

If  $S$  is an  $m \times n$  S-Box, then  $b \in \mathbb{F}_2^n$  and  $\cdot$  denotes dot product of two vectors.

INPUT:

- $b$  – either an integer or a list/tuple/vector of  $\mathbb{F}_2$  elements of length `self.output_size()`

EXAMPLES:

```

sage: from sage.crypto.sbox import SBox
sage: S = SBox([7,6,0,4,2,5,1,3])
sage: f3 = S.component_function(3)
sage: f3.algebraic_normal_form()
x0*x1 + x0*x2 + x0 + x2

sage: f5 = S.component_function([1, 0, 1])
sage: f5.algebraic_normal_form()
x0*x2 + x0 + x1*x2

```

### **derivative(*u*)**

Return the derivative in direction of  $u$

INPUT:

- $u$  – either an integer or a tuple/list of  $\mathbb{F}_2$  elements of length equal to  $m$

The derivative of  $F$  in direction of  $u$  is defined as  $x \mapsto F(x) + F(x + u)$ .

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: s = SBox(0,1,2,3)
sage: s.derivative(1)
(1, 1, 1, 1)
sage: u = [1,0]
sage: s.derivative(u)
(1, 1, 1, 1)
sage: v = vector(GF(2), [1,0])
sage: s.derivative(v)
(1, 1, 1, 1)
sage: s.derivative(4)
Traceback (most recent call last):
...
IndexError: list index out of range
sage: from sage.crypto.sboxes import PRESENT
sage: PRESENT.derivative(1).max_degree() < PRESENT.max_degree()
True
```

**difference\_distribution\_table()**

Return difference distribution table (DDT)  $A$  for this S-box.

The rows of  $A$  encode the differences  $\Delta I$  of the input and the columns encode the difference  $\Delta O$  for the output. The bits are ordered according to the endianness of this S-box. The value at  $A[\Delta I, \Delta O]$  encodes how often  $\Delta O$  is the actual output difference given  $\Delta I$  as input difference.

See [He2002] for an introduction to differential cryptanalysis.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: S.difference_distribution_table()
[8 0 0 0 0 0 0 0]
[0 2 2 0 2 0 0 2]
[0 0 2 2 0 0 2 2]
[0 2 0 2 2 0 2 0]
[0 2 0 2 0 2 0 2]
[0 0 2 2 2 2 0 0]
[0 2 2 0 0 2 2 0]
[0 0 0 0 2 2 2 2]
```

**differential\_branch\_number()**

Return differential branch number of this S-Box.

The differential branch number of an S-Box  $S$  is defined as

$$\min_{v,w \neq v} \{wt(v \oplus w) + wt(S(v) \oplus S(w))\},$$

where  $wt(x)$  denotes the Hamming weight of vector  $x$ .

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([12,5,6,11,9,0,10,13,3,14,15,8,4,7,1,2])
sage: S.differential_branch_number()
3
```

**differential\_uniformity()**

Return the difference probability of the difference with the highest probability in absolute terms, i.e. how often it occurs in total.

Equivalently, this is equal to the differential uniformity of this S-Box.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: S.maximal_difference_probability_absolute()
2
```

---

**Note:** This code is mainly called internally.

---

**fixed\_points()**

Return a list of all fixed points of this S-Box.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([0,1,3,6,7,4,5,2])
sage: S.fixed_points()
[0, 1]
```

**from\_bits(x, n=None)**

Return integer for bitstring x of length n.

INPUT:

- x – a bitstring
- n – bit length (optional)

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: S.from_bits( [1,1,0])
6

sage: S( S.from_bits( [1,1,0] ) )
1

sage: S.from_bits( S( [1,1,0] ) )
1
```

**has\_linear\_structure()**

Return True if there exists a nonzero component function of this S-Box that has a linear structure.

See also:

`is_linear_structure()`, `linear_structures()`.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(12,5,6,11,9,0,10,13,3,14,15,8,4,7,1,2)
sage: S.has_linear_structure()
True
```

**input\_size()**

Return the input size of this S-Box.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([0, 3, 2, 1, 1, 3, 2, 0])
sage: S.input_size()
3
```

**interpolation\_polynomial** ( $k=None$ )

Return a univariate polynomial over an extension field representing this S-box.

If  $m$  is the input length of this S-box then the extension field is of degree  $m$ .

If the output length does not match the input length then a `TypeError` is raised.

INPUT:

- $k$  – (optional) an instance of  $\mathbf{F}_{2^m}$

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: f = S.interpolation_polynomial()
sage: f
(a^2 + a + 1)*x^6 + a^2*x^5 + (a + 1)*x^4 + (a^2 + a)*x^3
+ x^2 + a*x + a^2 + a + 1

sage: a = f.base_ring().gen()

sage: f(0), S(0)
(a^2 + a + 1, 7)

sage: f(a^2 + 1), S(5)
(a^2 + 1, 5)
```

---

**Note:** The method-internal call to the S-box initially used a different endianness for handling finite field elements. This changed in [github issue #25633](#), by calling the S-box directly.

---

**inverse()**

Return the inverse of this S-Box.

Note that the S-Box must be invertible, otherwise it will raise a `TypeError`.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([0, 1, 3, 6, 7, 4, 5, 2])
sage: Sinv = S.inverse()
sage: [Sinv(S(i)) for i in range(8)]
[0, 1, 2, 3, 4, 5, 6, 7]
```

**is\_almost\_bent()**

Return True if this S-Box is an almost bent (AB) function.

An  $m \times m$  S-Box  $S$ , for  $m$  odd, is called almost bent if its nonlinearity is equal to  $2^{m-1} - 2^{(m-1)/2}$ .

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([0, 1, 3, 6, 7, 4, 5, 2])
sage: S.is_almost_bent()
True
```

**is\_apn()**

Return True if this S-Box is an almost perfect nonlinear (APN) function.

An  $m \times m$  S-Box  $S$  is called almost perfect nonlinear if for every nonzero  $\alpha \in \mathbf{F}_2^m$  and every  $\beta \in \mathbf{F}_2^m$ , the equation  $S(x) \oplus S(x \oplus \alpha) = \beta$  has 0 or 2 solutions. Equivalently, the differential uniformity of  $S$  is equal to 2.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([0, 1, 3, 6, 7, 4, 5, 2])
sage: S.is_apn()
True
sage: S.differential_uniformity()
2
```

**is\_balanced()**

Return True if this S-Box is balanced.

An S-Box is balanced if all its component functions are balanced.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([12, 5, 6, 11, 9, 0, 10, 13, 3, 14, 15, 8, 4, 7, 1, 2])
sage: S.is_balanced()
True
```

**is\_bent()**

Return True if this S-Box is bent, i.e. its nonlinearity is equal to  $2^{m-1} - 2^{m/2-1}$  where  $m$  is the input size of the S-Box.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: R.<x> = GF(2**2, 'a')[]
sage: base = R.base_ring()
sage: a = base.gen()
```

(continues on next page)

(continued from previous page)

```

sage: G = a * x^2 + 1
sage: S = SBox([[G(x * y**(14)) for x in sorted(base) for y in sorted(base]])
sage: S.is_bent()
True
sage: S.nonlinearity()
6
sage: S.linear_approximation_table()

[ 0 -2  2 -2]
[ 0  2  2  2]
[ 0  2 -2 -2]
[ 0 -2 -2  2]

```

**is\_involution()**

Return True if this S-Box is an involution, i.e. the inverse S-Box is equal itself.

EXAMPLES:

```

sage: from sage.crypto.sbox import SBox
sage: S = SBox([x**254 for x in sorted(GF(2**8))])
sage: S.is_involution()
True

```

**is\_linear\_structure(a, b)**

Return True if  $a$  is a linear structure of the component function  $b \cdot S(x)$  where  $S$  is this  $m \times n$  S-Box.

INPUT:

- $a$  – either an integer or a tuple of  $\mathbf{F}_2$  elements of length equal to the input size of SBox
- $b$  – either an integer or a tuple of  $\mathbf{F}_2$  elements of length equal to the output size of SBox

See also:

[\*linear\\_structures\(\)\*](#), [\*has\\_linear\\_structure\(\)\*](#)

EXAMPLES:

```

sage: from sage.crypto.sbox import SBox
sage: S = SBox(12,5,6,11,9,0,10,13,3,14,15,8,4,7,1,2)
sage: S.component_function(1).autocorrelation()
(16, -16, 0, 0, 0, 0, 0, 0, -16, 16, 0, 0, 0, 0, 0)
sage: S.is_linear_structure(1, 1)
True

```

(continues on next page)

(continued from previous page)

```
sage: S.is_linear_structure([1, 0, 0, 1], [0, 0, 0, 1])
True
sage: S.is_linear_structure([0, 1, 1, 1], 1)
False
```

**is\_monomial\_function()**

Return True if this S-Box is a monomial/power function.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([0,1,3,6,7,4,5,2])
sage: S.is_monomial_function()
False
sage: S_poly = S.interpolation_polynomial(); S_poly
(a + 1)*x^6 + (a^2 + a + 1)*x^5 + (a^2 + a)*x^4
+ (a^2 + 1)*x^3 + a*x^2 + a*x
sage: all([S(x) == S_poly(x) for x in S_poly.base_ring()])
True
sage: S = SBox(0,3,2,1)
sage: S.interpolation_polynomial()
x^2
sage: S.is_monomial_function()
True
```

**is\_permutation()**

Return True if this S-Box is a permutation.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: S.is_permutation()
True
sage: S = SBox(3,2,0,0,2,1,1,3)
sage: S.is_permutation()
False
```

**is\_plateaued()**

Return True if this S-Box is plateaued, i.e. for all nonzero  $b \in \mathbb{F}_2^n$  the Boolean function  $b \cdot S(x)$  is plateaued.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(0, 3, 1, 2, 4, 6, 7, 5)
sage: S.is_plateaued()
True
```

**linear\_approximation\_table(scale='absolute\_bias')**

Return linear approximation table (LAT)  $A$  for this S-box.

The entry  $A[\alpha, \beta]$  corresponds to the probability  $Pr[\alpha \cdot x = \beta \cdot S(x)]$ , where  $S$  is this S-box mapping  $n$ -bit inputs to  $m$ -bit outputs. There are three typical notations for this probability used in the literature:

- $Pr[\alpha \cdot x = \beta \cdot S(x)] = 1/2 + e(\alpha, \beta)$ , where  $e(\alpha, \beta)$  is called the bias,
- $2 \cdot Pr[\alpha \cdot x = \beta \cdot S(x)] = 1 + c(\alpha, \beta)$ , where  $c(\alpha, \beta) = 2 \cdot e(\alpha, \beta)$  is the correlation, and
- $2^{(m+1)} \cdot Pr[\alpha \cdot x = \beta \cdot S(x)] = 2^m + \hat{S}(\alpha, \beta)$ , where  $\hat{S}(\alpha, \beta)$  is the Fourier coefficient of  $S$ .

See [He2002] for an introduction to linear cryptanalysis.

INPUT:

- scale - string to choose the scaling for the LAT, one of
  - “bias”: elements are  $e(\alpha, \beta)$
  - “correlation”: elements are  $c(\alpha, \beta)$
  - “absolute\_bias”: elements are  $2^m \cdot e(\alpha, \beta)$  (default)
  - “fourier\_coefficient”: elements are  $\hat{S}(\alpha, \beta)$

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: lat_abs_bias = S.linear_approximation_table()
sage: lat_abs_bias
[ 4  0  0  0  0  0  0  0]
[ 0  0  0  0  2  2  2 -2]
[ 0  0 -2 -2 -2  2  0  0]
[ 0  0 -2  2  0  0 -2 -2]
[ 0  2  0  2 -2  0  2  0]
[ 0 -2  0  2  0  2  0  2]
[ 0 -2 -2  0  0 -2  2  0]
[ 0 -2  2  0 -2  0  0 -2]

sage: lat_abs_bias/(1 << S.input_size()) == S.linear_approximation_table(
↪ scale="bias")
True

sage: lat_abs_bias/(1 << (S.input_size()-1)) == S.linear_approximation_
↪ table(scale="correlation")
True

sage: lat_abs_bias*2 == S.linear_approximation_table(scale="fourier_coefficient
↪ ")
True
```

According to this table the first bit of the input is equal to the third bit of the output 6 out of 8 times:

```
sage: for i in xrange(8): print(S.to_bits(i)[0] == S.to_bits(S(i))[2])
False
True
True
True
False
True
```

(continues on next page)

(continued from previous page)

```
True
True
```

**linear\_branch\_number()**

Return linear branch number of this S-Box.

The linear branch number of an S-Box  $S$  is defined as

$$\min_{\substack{\alpha \neq 0, \beta \\ \text{LAM}(\alpha, \beta) \neq 0}} \{\text{wt}(\alpha) + \text{wt}(\beta)\},$$

where  $\text{LAM}(\alpha, \beta)$  is the entry at row  $\alpha$  and column  $\beta$  of linear approximation matrix correspond to this S-Box. The  $\text{wt}(x)$  denotes the Hamming weight of  $x$ .

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([12, 5, 6, 11, 9, 0, 10, 13, 3, 14, 15, 8, 4, 7, 1, 2])
sage: S.linear_branch_number()
2
```

**linear\_structures()**

Return a list of 3-valued tuple  $(b, \alpha, c)$  such that  $\alpha$  is a  $c$ -linear structure of the component function  $b \cdot S(x)$ .

A Boolean function  $f : \mathbf{F}_2^m \mapsto \mathbf{F}_2$  is said to have a  $c$ -linear structure if there exists a nonzero  $\alpha$  such that  $f(x) \oplus f(x \oplus \alpha)$  is a constant function  $c$ .

An  $m \times n$  S-Box  $S$  has a linear structure if there exists a component function  $b \cdot S(x)$  that has a linear structure.

The three valued tuple  $(b, \alpha, c)$  shows that  $\alpha$  is a  $c$ -linear structure of the component function  $b \cdot S(x)$ . This implies that for all output differences  $\beta$  of the S-Box correspond to input difference  $\alpha$ , we have  $b \cdot \beta = c$ .

See also:

[is\\_linear\\_structure\(\)](#), [has\\_linear\\_structure\(\)](#)

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([0, 1, 3, 6, 7, 4, 5, 2])
sage: S.linear_structures()
[(1, 1, 1), (2, 2, 1), (3, 3, 1), (4, 4, 1),
 (5, 5, 1), (6, 6, 1), (7, 7, 1)]
```

**linearity()**

Return the linearity of this S-Box.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = mq.SR(1, 4, 4, 8).sbox()
sage: S.linearity()
32
```

**max\_degree()**

Return the maximal algebraic degree of all its component functions.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([12,5,6,11,9,0,10,13,3,14,15,8,4,7,1,2])
sage: S.max_degree()
3
```

**maximal\_difference\_probability()**

Return the difference probability of the difference with the highest probability in the range between 0.0 and 1.0 indicating 0% or 100% respectively.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: S.maximal_difference_probability()
0.25
```

**maximal\_difference\_probability\_absolute()**

Return the difference probability of the difference with the highest probability in absolute terms, i.e. how often it occurs in total.

Equivalently, this is equal to the differential uniformity of this S-Box.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: S.maximal_difference_probability_absolute()
2
```

---

**Note:** This code is mainly called internally.

---

**maximal\_linear\_bias\_absolute()**

Return maximal linear bias, i.e. how often the linear approximation with the highest bias is true or false minus  $2^{n-1}$ .

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: S.maximal_linear_bias_absolute()
2
```

**maximal\_linear\_bias\_relative()**

Return maximal bias of all linear approximations of this S-box.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: S.maximal_linear_bias_relative()
0.25
```

**min\_degree()**

Return the minimal algebraic degree of all its component functions.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([12,5,6,11,9,0,10,13,3,14,15,8,4,7,1,2])
sage: S.min_degree()
2
```

### **nonlinearity()**

Return the nonlinearity of this S-Box.

The nonlinearity of an S-Box is defined as the minimum nonlinearity of all its component functions.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = mq.SR(1,4,4,8).sbox()
sage: S.nonlinearity()
112
```

### **output\_size()**

Return the output size of this S-Box.

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox([0, 3, 2, 1, 1, 3, 2, 0])
sage: S.output_size()
2
```

### **polynomials(*X=None, Y=None, degree=2, groebner=False*)**

Return a list of polynomials satisfying this S-box.

First, a simple linear fitting is performed for the given degree (cf. for example [BC2003]). If `groebner=True` a Groebner basis is also computed for the result of that process.

INPUT:

- `X` – (optional) input variables
- `Y` – (optional) output variables
- `degree` – (default: 2) integer > 0
- `groebner` – (default: False) calculate a reduced Groebner basis of the spanning polynomials to obtain more polynomials

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: P = S.ring()
```

By default, this method returns an indirect representation:

```
sage: S.polynomials()
[x0*x2 + x1 + y1 + 1,
 x0*x1 + x1 + x2 + y0 + y1 + y2 + 1,
 x0*y1 + x0 + x2 + y0 + y2,
```

(continues on next page)

(continued from previous page)

```

x0*y0 + x0*y2 + x1 + x2 + y0 + y1 + y2 + 1,
x1*x2 + x0 + x1 + x2 + y2 + 1,
x0*y0 + x1*y0 + x0 + x2 + y1 + y2,
x0*y0 + x1*y1 + x1 + y1 + 1,
x1*y2 + x1 + x2 + y0 + y1 + y2 + 1,
x0*y0 + x2*y0 + x1 + x2 + y1 + 1,
x2*y1 + x0 + y1 + y2,
x2*y2 + x1 + y1 + 1,
y0*y1 + x0 + x2 + y0 + y1 + y2,
y0*y2 + x1 + x2 + y0 + y1 + 1,
y1*y2 + x2 + y0]

```

We can get a direct representation by computing a lexicographical Groebner basis with respect to the right variable ordering, i.e. a variable ordering where the output bits are greater than the input bits:

```

sage: P.<y0,y1,y2,x0,x1,x2> = PolynomialRing(GF(2),6,order='lex')
sage: S.polynomials([x0,x1,x2],[y0,y1,y2], groebner=True)
[y0 + x0*x1 + x0*x2 + x0 + x1*x2 + x1 + 1,
 y1 + x0*x2 + x1 + 1,
 y2 + x0 + x1*x2 + x1 + x2 + 1]

```

**ring()**

Create, return, and cache a polynomial ring for S-box polynomials.

EXAMPLES:

```

sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: S.ring()
Multivariate Polynomial Ring in x0, x1, x2, y0, y1, y2 over Finite Field of 2
↳size 2

```

**solutions(X=None, Y=None)**

Return a dictionary of solutions to this S-box.

INPUT:

- X – (optional) input variables
- Y – (optional) output variables

EXAMPLES:

```

sage: from sage.crypto.sbox import SBox
sage: S = SBox([7,6,0,4,2,5,1,3])
sage: F = S.polynomials()
sage: s = S.solutions()
sage: any(f.subs(_s) for f in F for _s in s)
False

```

**to\_bits(x, n=None)**

Return bitstring of length n for integer x. The returned bitstring is guaranteed to have length n.

INPUT:

- x – an integer

- $n$  – bit length (optional)

EXAMPLES:

```
sage: from sage.crypto.sbox import SBox
sage: S = SBox(7,6,0,4,2,5,1,3)
sage: S.to_bits(6)
[1, 1, 0]

sage: S.to_bits( S(6) )
[0, 0, 1]

sage: S( S.to_bits( 6 ) )
[0, 0, 1]
```

`sage.crypto.sbox.feistel_construction(*args)`

Return an S-Box constructed by Feistel structure using smaller S-Boxes in `args`. The number of round in the construction is equal to the number of S-Boxes provided as input. For more results concerning the differential uniformity and the nonlinearity of S-Boxes constructed by Feistel structures see [CDL2015].

INPUT:

- `args` – a finite iterable SBox objects

EXAMPLES:

Suppose we construct an  $8 \times 8$  S-Box with 3-round Feistel construction from the S-Box of PRESENT:

```
sage: from sage.crypto.sbox import SBox
sage: s = SBox(12,5,6,11,9,0,10,13,3,14,15,8,4,7,1,2)
sage: from sage.crypto.sbox import feistel_construction
sage: S = feistel_construction(s, s, s)
```

The properties of the constructed S-Box can be easily examined:

```
sage: S.nonlinearity()
96
sage: S.differential_branch_number()
2
sage: S.linear_branch_number()
2
```

`sage.crypto.sbox.misty_construction(*args)`

Return an S-Box constructed by MISTY structure using smaller S-Boxes in `args`.

The number of round in the construction is equal to the number of S-Boxes provided as input. For further result related to the nonlinearity and differential uniformity of the constructed S-Box one may consult [CDL2015].

INPUT:

- `args` – a finite iterable SBox objects

EXAMPLES:

We construct an  $8 \times 8$  S-Box using 3-round MISTY structure with the following  $4 \times 4$  S-Boxes  $S_1, S_2, S_3$  (see Example 2 in [CDL2015]):

```
sage: from sage.crypto.sbox import SBox
sage: S1 = SBox([0x4, 0x0, 0x1, 0xF, 0x2, 0xB, 0x6, 0x7, 0x3, 0x9, 0xA, 0x5, 0xC, 0xD, 0xE, 0x8])
sage: S2 = SBox([0x0, 0x0, 0x0, 0x1, 0x0, 0xA, 0x8, 0x3, 0x0, 0x8, 0x2, 0xB, 0x4, 0x6, 0xE, 0xD])
sage: S3 = SBox([0x0, 0x7, 0xB, 0xD, 0x4, 0x1, 0xB, 0xF, 0x1, 0x2, 0xC, 0xE, 0xD, 0xC, 0x5, 0x5])
sage: from sage.crypto.sbox import misty_construction
sage: S = misty_construction(S1, S2, S3)
```

The properties of the constructed S-Box can be easily examined:

```
sage: S.differential_uniformity()
8
sage: S.linearity()
64
```

## S-BOXES USED IN CRYPTOGRAPHIC SCHEMES

This module provides the following SBoxes:

### constructions

- BrackenLeander ([BraLea2008])
- CarletTangTangLiao ([CTTL2014])

### 3 bit to 3 bit

- SEA ([SPGQ2006])
- PRINTcipher ([KLPR2010])
- Pyjamask\_3 ([GJKPRSS2019])

Additionally this module offers a dictionary *sboxes* of all implemented above S-boxes for the purpose of easy iteration over all available S-boxes.

### EXAMPLES:

We can print the S-Boxes with differential uniformity 2:

```
sage: from sage.crypto.sboxes import sboxes
sage: sorted(name for name, s in sboxes.items()
.....:         if s.differential_uniformity() == 2)
['APN_6',
 'Fides_5',
 'Fides_6',
 'PRINTcipher',
```

(continues on next page)

(continued from previous page)

```
'Pyjamask_3',
'SC2000_5',
'SEA',
'Shamash']
```

AUTHOR:

- Leo Perrin: initial collection of sboxes
- Friedrich Wiemer (2017-05-12): refactored list for inclusion in Sage
- Lukas Stennes (2019-06-25): added NIST LWC round 1 candidates

sage.crypto.sboxes.**bracken\_leander**(*n*)

Return the Bracken-Leander construction.

For  $n = 4 \cdot k$  and odd  $k$ , the construction is  $x \mapsto x^{2^{2k} + 2^k + 1}$  over  $\mathbf{F}_{2^n}$ .

INPUT:

- $n$  – size of the S-Box

EXAMPLES:

```
sage: from sage.crypto.sboxes import bracken_leander
sage: sbox = bracken_leander(12); [sbox(i) for i in range(8)]
[0, 1, 2742, 4035, 1264, 408, 1473, 1327]
```

sage.crypto.sboxes.**carlet\_tang\_tang\_liao**(*n*, *c=None*, *bf=None*)

Return the Carlet-Tang-Tang-Liao construction.

See [CTTL2014] for its definition.

INPUT:

- $n$  – integer, the bit length of inputs and outputs, has to be even and  $\geq 6$
- $c$  – element of  $\mathbf{F}_{2^{n-1}}$  used in the construction  
(default: random element)
- $f$  – Function from  $\mathbf{F}_{2^n} \rightarrow \mathbf{F}_2$  or BooleanFunction on  $n - 1$  bits  
(default:  $x \rightarrow (1/(x+1)).\text{trace}()$ )

EXAMPLES:

```
sage: from sage.crypto.sboxes import carlet_tang_tang_liao as cttl
sage: cttl(6).differential_uniformity() in [4, 64]
True
```

sage.crypto.sboxes.**gold**(*n*, *i*)

Return the Gold function defined by  $x \mapsto x^{2^i + 1}$  over  $\mathbf{F}_{2^n}$ .

INPUT:

- $n$  – size of the S-Box
- $i$  – a positive integer

EXAMPLES:

```
sage: from sage.crypto.sboxes import gold
sage: gold(3, 1)
(0, 1, 3, 4, 5, 6, 7, 2)
sage: gold(3, 1).differential_uniformity()
2
sage: gold(4, 2)
(0, 1, 6, 6, 7, 7, 7, 6, 1, 7, 1, 6, 1, 6, 7, 1)
```

`sage.crypto.sboxes.kasami(n, i)`

Return the Kasami function defined by  $x \mapsto x^{2^{2i}-2^i+1}$  over  $\mathbf{F}_{2^n}$ .

INPUT:

- $n$  – size of the S-Box
- $i$  – a positive integer

EXAMPLES:

```
sage: from sage.crypto.sboxes import kasami
sage: kasami(3, 1)
(0, 1, 3, 4, 5, 6, 7, 2)
sage: from sage.crypto.sboxes import gold
sage: kasami(3, 1) == gold(3, 1)
True
sage: kasami(4, 2)
(0, 1, 13, 11, 14, 9, 6, 7, 10, 4, 15, 2, 8, 3, 5, 12)
sage: kasami(4, 2) != gold(4, 2)
True
```

`sage.crypto.sboxes.monomial_function(n, e)`

Return an S-Box as a function  $x^e$  defined over  $\mathbf{F}_{2^n}$ .

INPUT:

- $n$  – size of the S-Box (i.e. the degree of the finite field extension)
- $e$  – exponent of the monomial function

EXAMPLES:

```
sage: from sage.crypto.sboxes import monomial_function
sage: S = monomial_function(7, 3)
sage: S.differential_uniformity()
2
sage: S.input_size()
7
sage: S.is_permutation()
True
```

`sage.crypto.sboxes.niho(n)`

Return the Niho function over  $\mathbf{F}_{2^n}$ .

It is defined by  $x \mapsto x^{2^t+2^s-1}$  with  $s = t/2$  if  $t$  is even or  $s = (3t + 1)/2$  if  $t$  is odd.

INPUT:

- $n$  – size of the S-Box

EXAMPLES:

```
sage: from sage.crypto.sboxes import niho
sage: niho(3)
(0, 1, 7, 2, 3, 4, 5, 6)

sage: niho(3).differential_uniformity()
2
```

`sage.crypto.sboxes.v(n)`

Return the Welch function defined by  $x \mapsto x^{2^{(n-1)/2}+3}$  over  $\mathbf{F}_{2^n}$ .

INPUT:

- $n$  – size of the S-Box

EXAMPLES:

```
sage: from sage.crypto.sboxes import welch
sage: welch(3)
(0, 1, 7, 2, 3, 4, 5, 6)
sage: welch(3).differential_uniformity()
2
```

`sage.crypto.sboxes.welch(n)`

Return the Welch function defined by  $x \mapsto x^{2^{(n-1)/2}+3}$  over  $\mathbf{F}_{2^n}$ .

INPUT:

- $n$  – size of the S-Box

EXAMPLES:

```
sage: from sage.crypto.sboxes import welch
sage: welch(3)
(0, 1, 7, 2, 3, 4, 5, 6)
sage: welch(3).differential_uniformity()
2
```

## ABSTRACT BASE CLASS FOR GENERATORS OF POLYNOMIAL SYSTEMS

AUTHOR:

Martin Albrecht <malb@informatik.uni-bremen.de>

**class** sage.crypto.mq.mpolynomialssystemgenerator.MPolynomialSystemGenerator

Bases: SageObject

Abstract base class for generators of polynomial systems.

**block\_order()**

Return a block term ordering for the equation systems generated by self.

EXAMPLES:

```
sage: from sage.crypto.mq.mpolynomialssystemgenerator import ↵
↳MPolynomialSystemGenerator
sage: msg = MPolynomialSystemGenerator()
sage: msg.block_order()
Traceback (most recent call last):
...
NotImplementedError
```

**polynomial\_system**(*P=None, K=None*)

Return a tuple *F,s* for plaintext *P* and key *K* where *F* is an polynomial system and *s* a dictionary which maps key variables to their solutions.

**INPUT:**

*P* – plaintext (vector, list) *K* – key (vector, list)

EXAMPLES:

```
sage: from sage.crypto.mq.mpolynomialssystemgenerator import ↵
↳MPolynomialSystemGenerator
sage: msg = MPolynomialSystemGenerator()
sage: msg.polynomial_system()
Traceback (most recent call last):
...
NotImplementedError
```

**random\_element()**

Return random element. Usually this is a list of elements in the base field of length ‘blocksize’.

EXAMPLES:

```
sage: from sage.crypto.mq.mpolynomialssystemgenerator import ↳
↳MPolynomialSystemGenerator
sage: msg = MPolynomialSystemGenerator()
sage: msg.random_element()
Traceback (most recent call last):
...
NotImplementedError
```

**ring()**

Return the ring in which the system is defined.

EXAMPLES:

```
sage: from sage.crypto.mq.mpolynomialssystemgenerator import ↳
↳MPolynomialSystemGenerator
sage: msg = MPolynomialSystemGenerator()
sage: msg.ring()
Traceback (most recent call last):
...
NotImplementedError
```

**sbox()**

Return SBox object for self.

EXAMPLES:

```
sage: from sage.crypto.mq.mpolynomialssystemgenerator import ↳
↳MPolynomialSystemGenerator
sage: msg = MPolynomialSystemGenerator()
sage: msg.sbox()
Traceback (most recent call last):
...
AttributeError: '<class 'sage.crypto.mq.mpolynomialssystemgenerator.
↳MPolynomialSystemGenerator'>' object has no attribute '_sbox'
```

**varformatstr(name)**

Return format string for a given name ‘name’ which is understood by print et al.

Such a format string is used to construct variable names. Typically those format strings are somewhat like ‘name%02d%02d’ such that rounds and offset in a block can be encoded.

**INPUT:**

name – string

EXAMPLES:

```
sage: from sage.crypto.mq.mpolynomialssystemgenerator import ↳
↳MPolynomialSystemGenerator
sage: msg = MPolynomialSystemGenerator()
sage: msg.varformatstr('K')
Traceback (most recent call last):
...
NotImplementedError
```

**vars(name, round)**

Return a list of variables given a name ‘name’ and an index ‘round’.

**INPUT:**

name – string round – integer index

**EXAMPLES:**

```
sage: from sage.crypto.mq.mpolynomialssystemgenerator import _
↳MPolynomialSystemGenerator
sage: msg = MPolynomialSystemGenerator()
sage: msg.vars('K',0)
Traceback (most recent call last):
...
NotImplementedError
```

**varstrs**(name, round)

Return a list of variable names given a name ‘name’ and an index ‘round’.

This function is typically used by self.\_vars.

**INPUT:**

name – string round – integer index

**EXAMPLES:**

```
sage: from sage.crypto.mq.mpolynomialssystemgenerator import _
↳MPolynomialSystemGenerator
sage: msg = MPolynomialSystemGenerator()
sage: msg.varstrs('K', i)
Traceback (most recent call last):
...
NotImplementedError
```

## SMALL SCALE VARIANTS OF THE AES (SR) POLYNOMIAL SYSTEM GENERATOR

Sage supports polynomial system generation for small scale (and full scale) AES variants over  $F_2$  and  $F_{2^e}$ . Also, Sage supports both the specification of SR as given in the papers [CMR2005] and [CMR2006] and a variant of SR\* which is equivalent to AES.

SR is a family of parameterizable variants of the AES suitable as a framework for comparing different cryptanalytic techniques that can be brought to bear on the AES. It is different from *Mini-AES*, whose purpose is as a teaching tool to help beginners understand the basic structure and working of the full AES.

AUTHORS:

- Martin Albrecht (2008,2009-01): usability improvements
- Martin Albrecht (2007-09): initial version
- Niles Johnson (2010-08): ([github issue #3893](#)) `random_element()` should pass on `*args` and `**kwargs`.

EXAMPLES:

We construct SR(1,1,1,4) and study its properties.

```
sage: sr = mq.SR(1, 1, 1, 4)
```

`n` is the number of rounds, `r` the number of rows in the state array, `c` the number of columns in the state array, and `e` the degree of the underlying field.

```
sage: sr.n, sr.r, sr.c, sr.e
(1, 1, 1, 4)
```

By default variables are ordered reverse to as they appear, e.g.:

```
sage: print(sr.R.repr_long())
Polynomial Ring
Base Ring : Finite Field in a of size 2^4
Size : 20 Variables
Block 0 : Ordering : deglex
Names : k100, k101, k102, k103, x100, x101, x102, x103, w100, w101,
↪w102, w103, s000, s001, s002, s003, k000, k001, k002, k003
```

However, this can be prevented by passing in `reverse_variables=False` to the constructor.

For SR(1, 1, 1, 4) the ShiftRows matrix isn't that interesting.:

```
sage: sr.ShiftRows
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

Also, the MixColumns matrix is the identity matrix.:

```
sage: sr.MixColumns
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

Lin, however, is not the identity matrix.:

```
sage: sr.Lin
[      a^2 + 1      1      a^3 + a^2      a^2 + 1]
[      a      a      1 a^3 + a^2 + a + 1]
[      a^3 + a      a^2      a^2      1]
[      1      a^3      a + 1      a + 1]
```

M and Mstar are identical for SR(1, 1, 1, 4):

```
sage: sr.M
[      a^2 + 1      1      a^3 + a^2      a^2 + 1]
[      a      a      1 a^3 + a^2 + a + 1]
[      a^3 + a      a^2      a^2      1]
[      1      a^3      a + 1      a + 1]
```

```
sage: sr.Mstar
[      a^2 + 1      1      a^3 + a^2      a^2 + 1]
[      a      a      1 a^3 + a^2 + a + 1]
[      a^3 + a      a^2      a^2      1]
[      1      a^3      a + 1      a + 1]
```

However, for larger instances of SR Mstar is not equal to M:

```
sage: sr = mq.SR(10,4,4,8)
sage: sr.Mstar == ~sr.MixColumns * sr.M
True
```

We can compute a Groebner basis for the ideals spanned by SR instances to recover all solutions to the system.:

```
sage: sr = mq.SR(1,1,1,4, gf2=True, polybori=True)
sage: K = sr.base_ring()
sage: a = K.gen()
sage: K = [a]
sage: P = [1]
sage: F,s = sr.polynomial_system(P=P, K=K)
sage: F.groebner_basis()
[k100, k101 + 1, k102, k103 + k003,
 x100 + 1, x101 + k003 + 1, x102 + k003 + 1,
```

(continues on next page)

(continued from previous page)

```
x103 + k003, w100, w101, w102 + 1, w103 + k003 + 1,
s000 + 1, s001 + k003, s002 + k003, s003 + k003 + 1,
k000, k001, k002 + 1]
```

Note that the order of  $k_{000}$ ,  $k_{001}$ ,  $k_{002}$  and  $k_{003}$  is little endian. Thus the result  $k_{002} + 1$ ,  $k_{001}$ ,  $k_{000}$  indicates that the key is either  $a$  or  $a + 1$ . We can verify that both keys encrypt  $P$  to the same ciphertext:

```
sage: sr(P,[a])
[0]
sage: sr(P,[a+1])
[0]
```

All solutions can easily be recovered using the variety function for ideals.:

```
sage: I = F.ideal()
sage: for V in I.variety():
.....:     for k,v in sorted(V.items()):
.....:         print("{} {}".format(k, v))
.....:     print("\n")
k003 0
k002 1
k001 0
k000 0
s003 1
s002 0
s001 0
s000 1
w103 1
w102 1
w101 0
w100 0
x103 0
x102 1
x101 1
x100 1
k103 0
k102 0
k101 1
k100 0

k003 1
k002 1
k001 0
k000 0
s003 0
s002 1
s001 1
s000 1
w103 0
w102 1
w101 0
w100 0
```

(continues on next page)

(continued from previous page)

```
x103 1
x102 0
x101 0
x100 1
k103 1
k102 0
k101 1
k100 0
```

We can also verify the correctness of the variety by evaluating all ideal generators on all points.:

```
sage: for V in I.variety():
.....:     for f in I.gens():
.....:         if f.subs(V) != 0:
.....:             print("epic fail")
```

Note that the S-Box object for SR can be constructed with a call to `sr.sbox()`:

```
sage: sr = mq.SR(1,1,1,4, gf2=True, polybori=True)
sage: S = sr.sbox()
```

For example, we can now study the difference distribution table of S:

```
sage: S.difference_distribution_table()
[16 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]
[ 0 2 2 2 2 0 0 0 2 0 0 0 2 4 0 0]
[ 0 2 0 4 2 2 2 0 0 2 0 0 0 0 0 2]
[ 0 2 4 0 0 2 0 0 2 2 0 2 0 0 2 0]
[ 0 0 2 0 4 2 0 0 0 0 2 0 2 0 2 2]
[ 0 0 0 2 0 0 0 2 4 2 0 0 2 0 2 2]
[ 0 4 0 0 0 2 0 2 0 2 2 0 2 2 0 0]
[ 0 2 0 0 0 0 2 0 0 0 0 2 4 2 2 2]
[ 0 2 2 0 0 0 2 2 2 0 2 0 0 0 0 4]
[ 0 0 2 2 0 0 0 0 0 2 2 4 0 2 0 2]
[ 0 0 2 0 2 0 2 2 0 4 0 2 2 0 0 0]
[ 0 0 0 0 2 0 2 0 2 2 4 0 0 2 2 0]
[ 0 0 0 2 0 4 2 0 2 0 2 2 2 0 0 0]
[ 0 0 0 0 2 2 0 4 2 0 0 2 0 2 0 2]
[ 0 0 2 2 0 2 4 2 0 0 0 0 0 2 2 0]
[ 0 2 0 2 2 0 0 2 0 0 2 2 0 0 4 0]
```

or use S to find alternative polynomial representations for the S-Box.:

```
sage: S.polynomials(degree=3)
[x0*x1 + x1*x2 + x0*x3 + x0*y2 + x1 + y0 + y1 + 1,
 x0*x1 + x0*x2 + x0*y0 + x0*y1 + x0*y2 + x1 + x2 + y0 + y1 + y2,
 x0*x1 + x0*x2 + x0*x3 + x1*x3 + x0*y0 + x1*y0 + x0*y1 + x0*y3,
 x0*x1 + x0*x2 + x0*x3 + x1*x3 + x0*y0 + x1*y1 + x0*y3 + x1 + y0 + y1 + 1,
 x0*x1 + x0*x2 + x0*y2 + x1*y2 + x0*y3 + x0 + x1,

**sage:** `S.interpolation_polynomial()`

```

(a^2 + 1)*x^14 + a^2*x^13 + x^12 + a^2*x^11 + a*x^10 + (a^3 + a)*x^9 +
(a^3 + 1)*x^7 + (a^3 + a^2 + a)*x^6 + a^2*x^5 + (a + 1)*x^4 + a^2*x^3 +
(a^3 + a^2 + a)*x^2 + (a^3 + 1)*x + a^2 + a

```

The `SR_gf2_2` gives an example how use alternative polynomial representations of the S-Box for construction of polynomial systems.

REFERENCES:

- [CMR2005]
- [CMR2006]
- [MR2002]

**class** `sage.crypto.mq.sr.AllowZeroInversionsContext`(*sr*)

Bases: `object`

Temporarily allow zero inversion.

`sage.crypto.mq.sr.SR`(*n=1, r=1, c=1, e=4, star=False, \*\*kwargs*)

Return a small scale variant of the AES polynomial system constructor subject to the following conditions:

INPUT:

- *n* - the number of rounds (default: 1)
- *r* - the number of rows in the state array (default: 1)
- *c* - the number of columns in the state array (default: 1)
- *e* - the exponent of the finite extension field (default: 4)
- *star* - determines if SR\* or SR should be constructed (default: `False`)
- *aes\_mode* - as the SR key schedule specification differs slightly from the AES key schedule, this parameter controls which schedule to use (default: `True`)
- *gf2* - generate polynomial systems over  $F_2$  rather than over  $F_{2^e}$  (default: `False`)
- *polybori* - use the `BooleanPolynomialRing` as polynomial representation (default: `True`,  $F_2$  only)

- `order` - a string to specify the term ordering of the variables (default: `deglex`)
- `postfix` - a string which is appended after the variable name (default: `'`)
- `allow_zero_inversions` - a boolean to control whether zero inversions raise an exception (default: `False`)
- `correct_only` - only include correct inversion polynomials (default: `False`,  $F_2$  only)
- `biaffine_only` - only include bilinear and biaffine inversion polynomials (default: `True`,  $F_2$  only)

EXAMPLES:

```
sage: sr = mq.SR(1, 1, 1, 4)
sage: ShiftRows = sr.shift_rows_matrix()
sage: MixColumns = sr.mix_columns_matrix()
sage: Lin = sr.lin_matrix()
sage: M = MixColumns * ShiftRows * Lin
sage: print(sr.hex_str_matrix(M))

```

**class** sage.crypto.mq.sr.SR\_generic(*n=1, r=1, c=1, e=4, star=False, \*\*kwargs*)

Bases: *MPolynomialSystemGenerator*

Small Scale Variants of the AES.

EXAMPLES:

```

sage: sr = mq.SR(1, 1, 1, 4)
sage: ShiftRows = sr.shift_rows_matrix()
sage: MixColumns = sr.mix_columns_matrix()
sage: Lin = sr.lin_matrix()
sage: M = MixColumns * ShiftRows * Lin
sage: print(sr.hex_str_matrix(M))
5 1 C 5
2 2 1 F
A 4 4 1
1 8 3 3

```

**add\_round\_key**(*d, key*)

Perform the AddRoundKey operation on *d* using *key*.

INPUT:

- *d* - state array or something coercible to a state array
- *key* - state array or something coercible to a state array

EXAMPLES:

```

sage: sr = mq.SR(10, 4, 4, 4)
sage: D = sr.random_state_array()
sage: K = sr.random_state_array()
sage: sr.add_round_key(D, K) == K + D
True

```

**base\_ring**()

Return the base field of self as determined by self.e.

EXAMPLES:

```

sage: sr = mq.SR(10, 2, 2, 4)
sage: sr.base_ring().polynomial()
a^4 + a + 1

```

The Rijndael polynomial:

```

sage: sr = mq.SR(10, 4, 4, 8)
sage: sr.base_ring().polynomial()
a^8 + a^4 + a^3 + a + 1

```

**block\_order()**

Return a block order for self where each round is a block.

EXAMPLES:

```
sage: sr = mq.SR(2, 1, 1, 4)
sage: sr.block_order()
Block term order with blocks:
(Degree lexicographic term order of length 16,
 Degree lexicographic term order of length 16,
 Degree lexicographic term order of length 4)
```

```
sage: P = sr.ring(order='block')
sage: print(P.repr_long())
Polynomial Ring
Base Ring : Finite Field in a of size 2^4
Size : 36 Variables
Block 0 : Ordering : deglex
Names : k200, k201, k202, k203, x200, x201, x202, x203, w200,
↵w201, w202, w203, s100, s101, s102, s103
Block 1 : Ordering : deglex
Names : k100, k101, k102, k103, x100, x101, x102, x103, w100,
↵w101, w102, w103, s000, s001, s002, s003
Block 2 : Ordering : deglex
Names : k000, k001, k002, k003
```

**hex\_str(*M*, typ='matrix')**

Return a hex string for the provided AES state array/matrix.

INPUT:

- *M* - state array
- *typ* - controls what to return, either 'matrix' or 'vector' (default: 'matrix')

EXAMPLES:

```
sage: sr = mq.SR(2, 2, 2, 4)
sage: k = sr.base_ring()
sage: A = matrix(k, 2, 2, [1, k.gen(), 0, k.gen()^2])
sage: sr.hex_str(A)
' 1 2 \n 0 4 \n'
```

```
sage: sr.hex_str(A, typ='vector')
'1024'
```

**hex\_str\_matrix(*M*)**

Return a two-dimensional AES-like representation of the matrix *M*.

That is, show the finite field elements as hex strings.

INPUT:

- *M* - an AES state array

EXAMPLES:

```

sage: sr = mq.SR(2, 2, 2, 4)
sage: k = sr.base_ring()
sage: A = matrix(k, 2, 2, [1, k.gen(), 0, k.gen()^2])
sage: sr.hex_str_matrix(A)
' 1 2 \n 0 4 \n'

```

**hex\_str\_vector(*M*)**

Return a one-dimensional AES-like representation of the matrix *M*.

That is, show the finite field elements as hex strings.

INPUT:

- *M* - an AES state array

EXAMPLES:

```

sage: sr = mq.SR(2, 2, 2, 4)
sage: k = sr.base_ring()
sage: A = matrix(k, 2, 2, [1, k.gen(), 0, k.gen()^2])
sage: sr.hex_str_vector(A)
'1024'

```

**is\_state\_array(*d*)**

Return True if *d* is a state array, i.e. has the correct dimensions and base field.

EXAMPLES:

```

sage: sr = mq.SR(2, 2, 4, 8)
sage: k = sr.base_ring()
sage: sr.is_state_array( matrix(k, 2, 4) )
True

```

```

sage: sr = mq.SR(2, 2, 4, 8)
sage: k = sr.base_ring()
sage: sr.is_state_array( matrix(k, 4, 4) )
False

```

**key\_schedule(*kj*, *i*)**

Return  $k_i$  for a given *i* and  $k_j$  with  $j = i - 1$ .

EXAMPLES:

```

sage: sr = mq.SR(10, 4, 4, 8, star=True, allow_zero_inversions=True)
sage: ki = sr.state_array()
sage: for i in range(10):
.....:     ki = sr.key_schedule(ki, i+1)
sage: print(sr.hex_str_matrix(ki))
B4 3E 23 6F
EF 92 E9 8F
5B E2 51 18
CB 11 CF 8E

```

**key\_schedule\_polynomials(*i*)**

Return polynomials for the *i*-th round of the key schedule.

INPUT:

- $i$  - round ( $0 \leq i \leq n$ )

EXAMPLES:

```
sage: sr = mq.SR(1, 1, 1, 4, gf2=True, polybori=False)
```

The 0-th subkey is the user provided key, so only conjugacy relations or field polynomials are added.:

```
sage: sr.key_schedule_polynomials(0)
(k000^2 + k000, k001^2 + k001, k002^2 + k002, k003^2 + k003)
```

The 1-th subkey is derived from the user provided key according to the key schedule which is non-linear.:

```
sage: sr.key_schedule_polynomials(1)
(k100 + s000 + s002 + s003,
 k101 + s000 + s001 + s003 + 1,
 k102 + s000 + s001 + s002 + 1,
 k103 + s001 + s002 + s003 + 1,
 k100^2 + k100, k101^2 + k101, k102^2 + k102, k103^2 + k103,
 s000^2 + s000, s001^2 + s001, s002^2 + s002, s003^2 + s003,
 s000*k000 + s000*k003 + s001*k002 + s002*k001 + s003*k000,
 s000*k000 + s000*k001 + s001*k000 + s001*k003 + s002*k002 + s003*k001,
 s000*k001 + s000*k002 + s001*k000 + s001*k001 + s002*k000 + s002*k003 +
↪s003*k002,
 s000*k000 + s000*k001 + s000*k003 + s001*k001 + s002*k000 + s002*k002 +
↪s003*k000 + k000,
 s000*k002 + s001*k000 + s001*k001 + s001*k003 + s002*k001 + s003*k000 +
↪s003*k002 + k001,
 s000*k000 + s000*k001 + s000*k002 + s001*k002 + s002*k000 + s002*k001 +

 s000*k002 + s001*k001 + s002*k000 + s003*k003 + 1)
```

### `mix_columns(d)`

Perform the MixColumns operation on  $d$ .

INPUT:

- $d$  - state array or something coercible to a state array

EXAMPLES:

```
sage: sr = mq.SR(10, 4, 4, 4)
sage: E = sr.state_array() + 1; E
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

```
sage: sr.mix_columns(E)
[  a a + 1      1      1]
[  1      a a + 1      1]
[  1      1      a a + 1]
[a + 1      1      1      a]
```

**new\_generator(\*\*kws)**

Return a new SR instance equal to this instance except for the parameters passed explicitly to this function.

INPUT:

- **\*\*kws** - see the SR constructor for accepted parameters

EXAMPLES:

```
sage: sr = mq.SR(2,1,1,4); sr
SR(2,1,1,4)
sage: sr.ring().base_ring()
Finite Field in a of size 2^4
```

```
sage: sr2 = sr.new_generator(gf2=True); sr2
SR(2,1,1,4)
sage: sr2.ring().base_ring()
Finite Field of size 2
sage: sr3 = sr2.new_generator(correct_only=True)
sage: len(sr2.inversion_polynomials_single_sbox())
20
sage: len(sr3.inversion_polynomials_single_sbox())
19
```

**polynomial\_system(P=None, K=None, C=None)**

Return a polynomial system for this small scale AES variant for a given plaintext-key pair.

If neither P, K nor C are provided, a random pair (P, K) will be generated. If P and C are provided no K needs to be provided.

INPUT:

- P - vector, list, or tuple (default: None)
- K - vector, list, or tuple (default: None)
- C - vector, list, or tuple (default: None)

EXAMPLES:

```
sage: sr = mq.SR(1, 1, 1, 4, gf2=True, polybori=True)
sage: P = sr.vector([0, 0, 1, 0])
sage: K = sr.vector([1, 0, 0, 1])
sage: F, s = sr.polynomial_system(P, K)
```

This returns a polynomial system:

```
sage: F
Polynomial Sequence with 36 Polynomials in 20 Variables
```

and a solution:

```
sage: s # random -- maybe we need a better doctest here?
{k000: 1, k001: 0, k003: 1, k002: 0}
```

This solution is not the only solution that we can learn from the Groebner basis of the system.

```
sage: F.groebner_basis()[-3:]
[k000 + 1, k001, k003 + 1]
```

In particular we have two solutions:

```
sage: len(F.ideal().variety())
2
```

In the following example we provide C explicitly:

```
sage: C = sr(P,K)
sage: F,s = sr.polynomial_system(P=P, C=C)
sage: F
Polynomial Sequence with 36 Polynomials in 20 Variables
```

Alternatively, we can use symbols for the P and C. First, we have to create a polynomial ring:

```
sage: sr = mq.SR(1, 1, 1, 4, gf2=True, polybori=True)
sage: R = sr.R
sage: vn = sr.varstrs("P",0,1,4) + R.variable_names() + sr.varstrs("C",0,1,4)
sage: R = BooleanPolynomialRing(len(vn),vn)
sage: sr.R = R
```

Now, we can construct the purely symbolic equation system:

```
sage: C = sr.vars("C",0); C
(C000, C001, C002, C003)
sage: P = sr.vars("P",0)
sage: F,s = sr.polynomial_system(P=P,C=C)
sage: F
Polynomial Sequence with 36 Polynomials in 28 Variables
sage: F.part(0)
(P000 + w100 + k000, P001 + w101 + k001, P002 + w102 + k002, P003 + w103 + k003)
sage: F.part(-2)
(k100 + x100 + x102 + x103 + C000, k101 + x100 + x101 + x103 + C001 + 1, ...)
```

We show that the (returned) key is a solution to the returned system:

```
sage: sr = mq.SR(3,4,4,8, star=True, gf2=True, polybori=True)
sage: while True: # workaround (see :trac:`31891`)
.....:     try:
.....:         F, s = sr.polynomial_system()
.....:         break
.....:     except ZeroDivisionError:
.....:         pass
sage: F.subs(s).groebner_basis() # long time
Polynomial Sequence with 1248 Polynomials in 1248 Variables
```

**random\_element**(*elem\_type*='vector', \*args, \*\*kwds)

Return a random element for self. Other arguments and keywords are passed to random\_\* methods.

INPUT:

- `elem_type` - either 'vector' or 'state array' (default: 'vector')

EXAMPLES:

```
sage: sr = mq.SR()
sage: sr.random_element().parent()
Full MatrixSpace of 4 by 1 dense matrices over Finite Field in a of size 2^4
sage: sr.random_element('state_array').parent()
Full MatrixSpace of 1 by 1 dense matrices over Finite Field in a of size 2^4
```

Passes extra positional or keyword arguments through:

```
sage: sr.random_element(density=0)
[0]
[0]
[0]
[0]
```

**random\_state\_array**(\*args, \*\*kws)

Return a random element in `MatrixSpace(self.base_ring(), self.r, self.c)`.

EXAMPLES:

```
sage: sr = mq.SR(2, 2, 2, 4)
sage: sr.random_state_array().parent()
Full MatrixSpace of 2 by 2 dense matrices over Finite Field in a of size 2^4
```

**random\_vector**(\*args, \*\*kws)

Return a random vector as it might appear in the algebraic expression of self.

EXAMPLES:

```
sage: mq.SR(2, 2, 2, 4).random_vector().parent()
Full MatrixSpace of 16 by 1 dense matrices over Finite Field in a of size 2^4
```

---

**Note:**  $\phi$  was already applied to the result.

---

**ring**(order=None, reverse\_variables=None)

Construct a ring as a base ring for the polynomial system.

By default, variables are ordered in the reverse of their natural ordering, i.e. the reverse of as they appear.

INPUT:

- `order` - a monomial ordering (default: None)
- `reverse_variables` - reverse rounds of variables (default: True)

The variable assignment is as follows:

- $k_{i,j,l}$  - subkey round  $i$  word  $j$  conjugate/bit  $l$
- $s_{i,j,l}$  - subkey inverse round  $i$  word  $j$  conjugate/bit  $l$
- $w_{i,j,l}$  - inversion input round  $i$  word  $j$  conjugate/bit  $l$
- $x_{i,j,l}$  - inversion output round  $i$  word  $j$  conjugate/bit  $l$

Note that the variables are ordered in column major ordering in the state array and that the bits are ordered in little endian ordering.

For example, if  $x_{0,1,0}$  is a variable over  $\mathbf{F}_2$  for  $r = 2$  and  $c = 2$  then refers to the *most* significant bit of the entry in the position (1,0) in the state array matrix.

EXAMPLES:

```
sage: sr = mq.SR(2, 1, 1, 4)
sage: P = sr.ring(order='block')
sage: print(P.repr_long())
Polynomial Ring
Base Ring : Finite Field in a of size 2^4
Size : 36 Variables
Block 0 : Ordering : deglex
Names : k200, k201, k202, k203, x200, x201, x202, x203, w200,
w201, w202, w203, s100, s101, s102, s103
Block 1 : Ordering : deglex
Names : k100, k101, k102, k103, x100, x101, x102, x103, w100,
w101, w102, w103, s000, s001, s002, s003
Block 2 : Ordering : deglex
Names : k000, k001, k002, k003
```

**round\_polynomials**( $i$ , *plaintext=None*, *ciphertext=None*)

Return list of polynomials for a given round  $i$ .

If  $i == 0$  a plaintext must be provided, if  $i == n$  a ciphertext must be provided.

INPUT:

- $i$  - round number
- *plaintext* - optional plaintext (mandatory in first round)
- *ciphertext* - optional ciphertext (mandatory in last round)

OUTPUT: tuple

EXAMPLES:

```
sage: sr = mq.SR(1, 1, 1, 4)
sage: k = sr.base_ring()
sage: p = [k.random_element() for _ in range(sr.r*sr.c)]
sage: sr.round_polynomials(0, plaintext=p)
(w100 + k000..., w101 + k001..., w102 + k002..., w103 + k003...)
```

**sbox**(*inversion\_only=False*)

Return an S-Box object for this SR instance.

INPUT:

- *inversion\_only* - do not include the  $\mathbf{F}_2$  affine map when computing the S-Box (default: False)

EXAMPLES:

```
sage: sr = mq.SR(1,2,2,4, allow_zero_inversions=True)
sage: S = sr.sbox(); S
(6, 11, 5, 4, 2, 14, 7, 10, 9, 13, 15, 12, 3, 1, 0, 8)
```

```

sage: S(1)
124
sage: sr = mq.SR(1,2,2,4, allow_zero_inversions=True)
sage: S = sr.sbox(inversion_only=True); S
(0, 1, 9, 14, 13, 11, 7, 6, 15, 2, 12, 5, 10, 4, 3, 8)
sage: S(0)
0
sage: S(1)
1
sage: S(sr.k.gen())
a^3 + a + 1

```

**sbox\_constant()**

Return the S-Box constant which is added after  $L(x^{-1})$  was performed. That is 0x63 if  $e == 8$  or 0x6 if  $e == 4$ .

EXAMPLES:

```

sage: sr = mq.SR(10, 1, 1, 8)
sage: sr.sbox_constant()
a^6 + a^5 + a + 1

```

**shift\_rows(d)**

Perform the ShiftRows operation on d.

INPUT:

- d - state array or something coercible to a state array

EXAMPLES:

```

sage: sr = mq.SR(10, 4, 4, 4)
sage: E = sr.state_array() + 1; E
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

```

```

sage: sr.shift_rows(E)
[1 0 0 0]
[1 0 0 0]
[1 0 0 0]
[1 0 0 0]

```

**state\_array(d=None)**

Convert the parameter to a state array.

INPUT:

- d - a matrix, a list, or a tuple (default: None)

EXAMPLES:

```

sage: sr = mq.SR(2, 2, 2, 4)
sage: k = sr.base_ring()
sage: e1 = [k.from_integer(e) for e in range(2*2)]; e1
[0, 1, a, a + 1]
sage: e2 = sr.phi( Matrix(k, 2*2, 1, e1) )
sage: sr.state_array(e1) # note the column major ordering
[  0  a]
[  1 a + 1]
sage: sr.state_array(e2)
[  0  a]
[  1 a + 1]

```

```

sage: sr.state_array()
[0 0]
[0 0]

```

### sub\_byte(b)

Perform SubByte on a single byte/halfbyte b.

A ZeroDivision exception is raised if an attempt is made to perform an inversion on the zero element. This can be disabled by passing allow\_zero\_inversion=True to the constructor. A zero inversion can result in an inconsistent equation system.

INPUT:

- b - an element in self.base\_ring()

EXAMPLES:

The S-Box table for  $F_{2^4}$ :

```

sage: sr = mq.SR(1, 1, 1, 4, allow_zero_inversions=True)
sage: for e in sr.base_ring():
.....:     print('% 20s % 20s'%(e, sr.sub_byte(e)))
          0                a^2 + a
          a                a^2 + 1
          a^2              a
          a^3              a^3 + 1
          a + 1            a^2
          a^2 + a          a^2 + a + 1
          a^3 + a^2        a + 1
          a^3 + a + 1      a^3 + a^2
          a^2 + 1          a^3 + a^2 + a
          a^3 + a          a^3 + a^2 + a + 1
          a^2 + a + 1      a^3 + a
          a^3 + a^2 + a    0
a^3 + a^2 + a + 1        a^3
          a^3 + a^2 + 1    1
          a^3 + 1          a^3 + a^2 + 1
          1                a^3 + a + 1

```

### sub\_bytes(d)

Perform the non-linear transform on d.

INPUT:

- `d` - state array or something coercible to a state array

EXAMPLES:

```
sage: sr = mq.SR(2, 1, 2, 8, gf2=True)
sage: k = sr.base_ring()
sage: A = Matrix(k, 1, 2, [k(1), k.gen()])
sage: sr.sub_bytes(A)
[ a^6 + a^5 + a^4 + a^3 + a^2 a^6 + a^5 + a^4 + a^2 + a + 1]
```

**varformatstr**(*name*, *n=None*, *rc=None*, *e=None*)

Return a format string which is understood by `print` et al.

If a numerical value is omitted, the default value of `self` is used. The numerical values (`n`, `rc`, `e`) are used to determine the width of the respective fields in the format string.

INPUT:

- `name` - name of the variable
- `n` - number of rounds (default: `None`)
- `rc` - number of rows \* number of cols (default: `None`)
- `e` - exponent of base field (default: `None`)

EXAMPLES:

```
sage: sr = mq.SR(1, 2, 2, 4)
sage: sr.varformatstr('x')
'x%01d%01d%01d'
sage: sr.varformatstr('x', n=1000)
'x%03d%03d%03d'
```

**variable\_dict**()

Return a dictionary to access variables in `self.R` by their names.

EXAMPLES:

```
sage: sr = mq.SR(1,1,1,4)
sage: sr.variable_dict()
{'k000': k000,
 'k001': k001,
 'k002': k002,
 'k003': k003,
 'k100': k100,
 'k101': k101,
 'k102': k102,
 'k103': k103,
 's000': s000,
 's001': s001,
 's002': s002,
 's003': s003,
 'w100': w100,
 'w101': w101,
 'w102': w102,
 'w103': w103,
 'x100': x100,
```

(continues on next page)

(continued from previous page)

```

'x101': x101,
'x102': x102,
'x103': x103}

sage: sr = mq.SR(1,1,1,4,gf2=True)
sage: sr.variable_dict()
{'k000': k000,
 'k001': k001,
 'k002': k002,
 'k003': k003,
 'k100': k100,
 'k101': k101,
 'k102': k102,
 'k103': k103,
 's000': s000,
 's001': s001,
 's002': s002,
 's003': s003,
 'w100': w100,
 'w101': w101,
 'w102': w102,
 'w103': w103,
 'x100': x100,
 'x101': x101,
 'x102': x102,
 'x103': x103}

```

**vars**(name, nr, rc=None, e=None)

Return a list of variables in self.

INPUT:

- name - variable name
- nr - number of round to create variable strings for
- rc - number of rounds \* number of columns in the state array (default: None)
- e - exponent of base field (default: None)

EXAMPLES:

```

sage: sr = mq.SR(10, 1, 2, 4)
sage: sr.vars('x', 2)
(x200, x201, x202, x203, x210, x211, x212, x213)

```

**varstr**(name, nr, rc, e)

Return a string representing a variable for the small scale AES subject to the given constraints.

INPUT:

- name - variable name
- nr - number of round to create variable strings for
- rc - row\*column index in state array
- e - exponent of base field

EXAMPLES:

```
sage: sr = mq.SR(10, 1, 2, 4)
sage: sr.varstr('x', 2, 1, 1)
'x211'
```

**varstrs**(*name, nr, rc=None, e=None*)

Return a list of strings representing variables in `self`.

INPUT:

- `name` - variable name
- `nr` - number of round to create variable strings for
- `rc` - number of rows \* number of columns in the state array (default: `None`)
- `e` - exponent of base field (default: `None`)

EXAMPLES:

```
sage: sr = mq.SR(10, 1, 2, 4)
sage: sr.varstrs('x', 2)
('x200', 'x201', 'x202', 'x203', 'x210', 'x211', 'x212', 'x213')
```

**class** `sage.crypto.mq.sr.SR_gf2`(*n=1, r=1, c=1, e=4, star=False, \*\*kwargs*)

Bases: `SR_generic`

Small Scale Variants of the AES polynomial system constructor over  $\mathbb{F}_2$ . See help for `SR`.

EXAMPLES:

```
sage: sr = mq.SR(gf2=True)
sage: sr
SR(1,1,1,4)
```

**antiphi**(*l*)

The operation  $\phi^{-1}$  from [MR2002] or the inverse of `self.phi`.

INPUT:

- `l` - a vector in the sense of `self.is_vector`

EXAMPLES:

```
sage: sr = mq.SR(gf2=True)
sage: A = sr.random_state_array()
sage: sr.antiphi(sr.phi(A)) == A
True
```

**field\_polynomials**(*name, i, l=None*)

Return list of field polynomials for a given round `i` and name `name`.

INPUT:

- `name` - variable name
- `i` - round number
- `l` - length of variable list (default: `None = r*c`)

EXAMPLES:

```
sage: sr = mq.SR(3, 1, 1, 8, gf2=True, polybori=False)
sage: sr.field_polynomials('x', 2)
[x200^2 + x200, x201^2 + x201,
 x202^2 + x202, x203^2 + x203,
 x204^2 + x204, x205^2 + x205,
 x206^2 + x206, x207^2 + x207]
```

```
sage: sr = mq.SR(3, 1, 1, 8, gf2=True, polybori=True)
sage: sr.field_polynomials('x', 2)
[]
```

**inversion\_polynomials**(*xi*, *wi*, *length*)

Return polynomials to represent the inversion in the AES S-Box.

INPUT:

- *xi* - output variables
- *wi* - input variables
- *length* - length of both lists

EXAMPLES:

```
sage: sr = mq.SR(1, 1, 1, 8, gf2=True)
sage: xi = sr.vars('x', 1)
sage: wi = sr.vars('w', 1)
sage: sr.inversion_polynomials(xi, wi, len(xi))[:3]

```

**inversion\_polynomials\_single\_sbox**(*x=None*, *w=None*, *biaffine\_only=None*, *correct\_only=None*)

Return inversion polynomials of a single S-Box.

INPUT:

- *xi* - output variables
- *wi* - input variables
- *length* - length of both lists

EXAMPLES:

```
sage: sr = mq.SR(1, 1, 1, 8, gf2=True)
sage: len(sr.inversion_polynomials_single_sbox())
24
sage: len(sr.inversion_polynomials_single_sbox(correct_only=True))
23
```

(continues on next page)

(continued from previous page)

```

sage: len(sr.inversion_polynomials_single_sbox(biaffine_only=False))
40
sage: len(sr.inversion_polynomials_single_sbox(biaffine_only=False, correct_
↳only=True))
39

sage: sr = mq.SR(1, 1, 1, 8, gf2=True)
sage: l0 = sr.inversion_polynomials_single_sbox(); len(l0)
24
sage: l1 = sr.inversion_polynomials_single_sbox(correct_only=True); len(l1)
23
sage: l2 = sr.inversion_polynomials_single_sbox(biaffine_only=False); len(l2)
40
sage: l3 = sr.inversion_polynomials_single_sbox(biaffine_only=False, correct_
↳only=True); len(l3)
39

sage: set(l0) == set(sr._inversion_polynomials_single_sbox())
True
sage: set(l1) == set(sr._inversion_polynomials_single_sbox(correct_only=True))
True
sage: set(l2) == set(sr._inversion_polynomials_single_sbox(biaffine_only=False))
True
sage: set(l3) == set(sr._inversion_polynomials_single_sbox(biaffine_only=False,
↳correct_only=True))
True

sage: sr = mq.SR(1, 1, 1, 4, gf2=True)
sage: l0 = sr.inversion_polynomials_single_sbox(); len(l0)
12
sage: l1 = sr.inversion_polynomials_single_sbox(correct_only=True); len(l1)
11
sage: l2 = sr.inversion_polynomials_single_sbox(biaffine_only=False); len(l2)
20
sage: l3 = sr.inversion_polynomials_single_sbox(biaffine_only=False, correct_
↳only=True); len(l3)
19

sage: set(l2) == set(sr._inversion_polynomials_single_sbox(biaffine_only=False))
True
sage: set(l3) == set(sr._inversion_polynomials_single_sbox(biaffine_only=False,
↳correct_only=True))
True

```

**is\_vector(*d*)**

Return True if the given matrix satisfies the conditions for a vector as it appears in the algebraic expression of self.

INPUT:

- d - matrix

EXAMPLES:

```
sage: sr = mq.SR(gf2=True)
sage: sr
SR(1,1,1,4)
sage: k = sr.base_ring()
sage: A = Matrix(k, 1, 1, [k.gen()])
sage: B = sr.vector(A)
sage: sr.is_vector(A)
False
sage: sr.is_vector(B)
True
```

**lin\_matrix**(length=None)

Return the Lin matrix.

If no length is provided, the standard state space size is used. The key schedule calls this method with an explicit length argument because only self.r S-Box applications are performed in the key schedule.

INPUT:

- length - length of state space (default: None)

EXAMPLES:

```
sage: sr = mq.SR(1, 1, 1, 4, gf2=True)
sage: sr.lin_matrix()
[1 0 1 1]
[1 1 0 1]
[1 1 1 0]
[0 1 1 1]
```

**mix\_columns\_matrix**()

Return the MixColumns matrix.

EXAMPLES:

```
sage: sr = mq.SR(1, 2, 2, 4, gf2=True)
sage: s = sr.random_state_array()
sage: r1 = sr.mix_columns(s)
sage: r2 = sr.state_array(sr.mix_columns_matrix() * sr.vector(s))
sage: r1 == r2
True
```

**phi**(l, diffusion\_matrix=False)

The operation  $\phi$  from [MR2002]

Given a list/matrix of elements in  $\mathbf{F}_{2^e}$ , return a matching list/matrix of elements in  $\mathbf{F}_2$ .

INPUT:

- l - element to perform  $\phi$  on.
- diffusion\_matrix - if True, the given matrix l is transformed to a matrix which performs the same operation over  $\mathbf{F}_2$  as l over  $\mathbf{F}_{2^n}$  (default: False).

EXAMPLES:

```
sage: sr = mq.SR(2, 1, 2, 4, gf2=True)
sage: k = sr.base_ring()
sage: A = matrix(k, 1, 2, [k.gen(), 0] )
sage: sr.phi(A)
[0 0]
[0 0]
[1 0]
[0 0]
```

### shift\_rows\_matrix()

Return the ShiftRows matrix.

EXAMPLES:

```
sage: sr = mq.SR(1, 2, 2, 4, gf2=True)
sage: s = sr.random_state_array()
sage: r1 = sr.shift_rows(s)
sage: r2 = sr.state_array( sr.shift_rows_matrix() * sr.vector(s) )
sage: r1 == r2
True
```

### vector(*d=None*)

Constructs a vector suitable for the algebraic representation of SR.

INPUT:

- *d* - values for vector (default: None)

EXAMPLES:

```
sage: sr = mq.SR(gf2=True)
sage: sr
SR(1,1,1,4)
sage: k = sr.base_ring()
sage: A = Matrix(k, 1, 1, [k.gen()])
sage: sr.vector(A)
[0]
[0]
[1]
[0]
```

**class** sage.crypto.mq.sr.SR\_gf2\_2(*n=1, r=1, c=1, e=4, star=False, \*\*kwargs*)

Bases: *SR\_gf2*

This is an example how to customize the SR constructor.

In this example, we replace the S-Box inversion polynomials by the polynomials generated by the S-Box class.

**inversion\_polynomials\_single\_sbox**(*x=None, w=None, biaffine\_only=None, correct\_only=None, groebner=False*)

Return inversion polynomials of a single S-Box.

INPUT:

- *x* - output variables (default: None)
- *w* - input variables (default: None)

- `biaffine_only` - ignored (always False)
- `correct_only` - ignored (always True)
- `groebner` - precompute the Groebner basis for this S-Box (default: False).

EXAMPLES:

```

sage: from sage.crypto.mq.sr import SR_gf2_2
sage: e = 4
sage: sr = SR_gf2_2(1, 1, 1, e)
sage: P = PolynomialRing(GF(2), ['x%d'%i for i in range(e)] + ['w%d'%i for i in
↳range(e)], order='lex')
sage: X, W = P.gens()[:e], P.gens()[e:]
sage: sr.inversion_polynomials_single_sbox(X, W, groebner=True)
[x0 + w0*w1*w2 + w0*w1 + w0*w2 + w0*w3 + w0 + w1 + w2,
 x1 + w0*w1*w3 + w0*w3 + w0 + w1*w3 + w1 + w2*w3,
 x2 + w0*w2*w3 + w0*w2 + w0 + w1*w2 + w1*w3 + w2*w3,
 x3 + w0*w1*w2 + w0 + w1*w2*w3 + w1*w2 + w1*w3 + w1 + w2 + w3]

sage: from sage.crypto.mq.sr import SR_gf2_2
sage: e = 4
sage: sr = SR_gf2_2(1, 1, 1, e)
sage: sr.inversion_polynomials_single_sbox()
[w3*w1 + w3*w0 + w3*x2 + w3*x1 + w3 + w2*w1 + w1 + x3 + x2 + x1,
 w3*w2 + w3*w1 + w3*x3 + w2 + w1 + x3,
 w3*w2 + w3*w1 + w3*x2 + w3 + w2*x3 + x2 + x1,
 w3*w2 + w3*w1 + w3*x3 + w3*x2 + w3*x1 + w3 + w2*x2 + w0 + x3 + x2 + x1 + x0,
 w3*w2 + w3*w1 + w3*x1 + w3*x0 + w2*x1 + w0 + x3 + x0,
 w3*w2 + w3*w1 + w3*w0 + w3*x2 + w3*x1 + w2*w0 + w2*x0 + w0 + x3 + x2 + x1 + x0,
 w3*w2 + w3*x1 + w3 + w2*w0 + w1*w0 + w1 + x3 + x2,
 w3*w2 + w3*w1 + w3*x1 + w1*x3 + x3 + x2 + x1,
 w3*x3 + w3*x2 + w3*x0 + w3 + w1*x2 + w1 + w0 + x2 + x0,
 w3*w2 + w3*w1 + w3*x2 + w3*x1 + w1*x1 + w1 + w0 + x2 + x0,
 w3*w2 + w3*w1 + w3*w0 + w3*x3 + w3*x1 + w2*w0 + w1*x0 + x3 + x2,
 w3*w2 + w3*w1 + w3*x2 + w3*x1 + w3*x0 + w3 + w1 + w0*x3 + x3 + x2,
 w3*w2 + w3*w1 + w3*w0 + w3*x3 + w3 + w2*w0 + w1 + w0*x2 + x3 + x2,
 w3*w0 + w3*x2 + w2*w0 + w0*x1 + w0 + x3 + x1 + x0,
 w3*w0 + w3*x3 + w3*x0 + w2*w0 + w1 + w0*x0 + w0 + x3 + x2,
 w3*w2 + w3 + w1 + x3*x2 + x3 + x1,
 w3*w2 + w3*x3 + w1 + x3*x1 + x3 + x2,
 w3*w2 + w3*w0 + w3*x3 + w3*x2 + w3*x1 + w0 + x3*x0 + x1 + x0,
 w3*w2 + w3*w1 + w3*w0 + w3*x3 + w1 + w0 + x2*x1 + x2 + x0,
 w3*w2 + w2*w0 + w1 + x3 + x2*x0,
 w3*x3 + w3*x1 + w2*w0 + w1 + x3 + x2 + x1*x0 + x1]

```

`class sage.crypto.mq.sr.SR_gf2n(n=1, r=1, c=1, e=4, star=False, **kwargs)`

Bases: `SR_generic`

Small Scale Variants of the AES polynomial system constructor over  $F_{2^n}$ .

`antiphi(l)`

The operation  $\phi^{-1}$  from [MR2002] or the inverse of `self.phi`.

INPUT:

- `l` – a vector in the sense of `is_vector()`

EXAMPLES:

```
sage: sr = mq.SR()
sage: A = sr.random_state_array()
sage: sr.antiphi(sr.phi(A)) == A
True
```

**field\_polynomials**(*name, i, l=None*)

Return list of conjugacy polynomials for a given round *i* and name *name*.

INPUT:

- *name* - variable name
- *i* - round number
- *l* - *r\*c* (default: *None*)

EXAMPLES:

```
sage: sr = mq.SR(3, 1, 1, 8)
sage: sr.field_polynomials('x', 2)
[x200^2 + x201,
x201^2 + x202,
x202^2 + x203,
x203^2 + x204,
x204^2 + x205,
x205^2 + x206,
x206^2 + x207,
x207^2 + x200]
```

**inversion\_polynomials**(*xi, wi, length*)

Return polynomials to represent the inversion in the AES S-Box.

INPUT:

- *xi* - output variables
- *wi* - input variables
- *length* - length of both lists

EXAMPLES:

```
sage: sr = mq.SR(1, 1, 1, 8)
sage: R = sr.ring()
sage: xi = Matrix(R, 8, 1, sr.vars('x', 1))
sage: wi = Matrix(R, 8, 1, sr.vars('w', 1))
sage: sr.inversion_polynomials(xi, wi, 8)
[x100*w100 + 1,
x101*w101 + 1,
x102*w102 + 1,
x103*w103 + 1,
x104*w104 + 1,
x105*w105 + 1,
x106*w106 + 1,
x107*w107 + 1]
```

**is\_vector(*d*)**

Return True if *d* can be used as a vector for *self*.

EXAMPLES:

```
sage: sr = mq.SR()
sage: sr
SR(1,1,1,4)
sage: k = sr.base_ring()
sage: A = Matrix(k, 1, 1, [k.gen()])
sage: B = sr.vector(A)
sage: sr.is_vector(A)
False
sage: sr.is_vector(B)
True
```

**lin\_matrix(*length=None*)**

Return the Lin matrix.

If no *length* is provided, the standard state space size is used. The key schedule calls this method with an explicit *length* argument because only *self.r* S-Box applications are performed in the key schedule.

INPUT:

- *length* - length of state space (default: None)

EXAMPLES:

```
sage: sr = mq.SR(1, 1, 1, 4)
sage: sr.lin_matrix()
[      a^2 + 1      1      a^3 + a^2      a^2 + 1]
[      a      a      1 a^3 + a^2 + a + 1]
[      a^3 + a      a^2      a^2      1]
[      1      a^3      a + 1      a + 1]
```

**mix\_columns\_matrix()**

Return the MixColumns matrix.

EXAMPLES:

```
sage: sr = mq.SR(1, 2, 2, 4)
sage: s = sr.random_state_array()
sage: r1 = sr.mix_columns(s)
sage: r2 = sr.state_array(sr.mix_columns_matrix() * sr.vector(s))
sage: r1 == r2
True
```

**phi(*l*)**

The operation  $\phi$  from [MR2002]

Projects state arrays to their algebraic representation.

INPUT:

- *l* - element to perform  $\phi$  on.

EXAMPLES:

```

sage: sr = mq.SR(2, 1, 2, 4)
sage: k = sr.base_ring()
sage: A = matrix(k, 1, 2, [k.gen(), 0] )
sage: sr.phi(A)
[      a      0]
[     a^2      0]
[   a + 1      0]
[ a^2 + 1      0]

```

**shift\_rows\_matrix()**

Return the ShiftRows matrix.

EXAMPLES:

```

sage: sr = mq.SR(1, 2, 2, 4)
sage: s = sr.random_state_array()
sage: r1 = sr.shift_rows(s)
sage: r2 = sr.state_array( sr.shift_rows_matrix() * sr.vector(s) )
sage: r1 == r2
True

```

**vector(*d=None*)**

Constructs a vector suitable for the algebraic representation of SR, i.e. BES.

INPUT:

- *d* - values for vector, must be understood by `self.phi` (default:None)

EXAMPLES:

```

sage: sr = mq.SR()
sage: sr
SR(1,1,1,4)
sage: k = sr.base_ring()
sage: A = Matrix(k, 1, 1, [k.gen()])
sage: sr.vector(A)
[      a]
[     a^2]
[   a + 1]
[ a^2 + 1]

```

**sage.crypto.mq.sr.test\_consistency(*max\_n=2, \*\*kwargs*)**

Test all combinations of *r*, *c*, *e* and *n* in (1, 2) for consistency of random encryptions and their polynomial systems.  $\mathbf{F}_2$  and  $\mathbf{F}_{2^e}$  systems are tested. This test takes a while.

INPUT:

- *max\_n* – maximal number of rounds to consider (default: 2)
- *kwargs* – are passed to the SR constructor

## RIJNDAEL-GF

Rijndael-GF is an algebraic implementation of the AES cipher which seeks to provide a fully generalized algebraic representation of both the whole AES cipher as well as its individual components.

This class is an algebraic implementation of the Rijndael-GF extension of the AES cipher, as described in [DR2002]. The AES cipher itself is defined to operate on a state in  $(\mathbb{F}_2)^{8n_t}$  where  $n_t \in \{16, 20, 24, 28, 32\}$ . Rijndael-GF is a generalization of AES which allows for operations in  $(\mathbb{F}_{2^s})^{n_t}$ , enabling more algebraically sophisticated study of AES and its variants. This implementation of Rijndael-GF is suitable for learning purposes, for comparison to other algebraic ciphers, and for studying various techniques of algebraic cryptanalysis of AES. This cipher is different from *Mini-AES*, which is a teaching tool for beginners to understand the basic structure of AES.

An algebraic implementation of Rijndael-GF is achieved by recognizing that for each round component function  $\phi$  of AES (SubBytes, ShiftRows, etc.) operating on state matrices, every entry of the output matrix  $B = \phi(A)$  is representable as a polynomial with variables being the entries of the input state matrix  $A$ . Correspondingly, this implementation of Rijndael-GF provides a `RijndaelGF.Round_Component_Poly_Constr` class which allows for creation of these such polynomials. For each round component function  $\phi$  of Rijndael-GF there exists a `Round_Component_Poly_Constr` object with a `__call__` method of the form `__call__(i, j)` which returns a polynomial representing  $\phi(A)_{i,j}$  in terms of the entries of  $A$ . There additionally are various methods provided which allow for easy polynomial evaluation and for simple creation of `Round_Component_Poly_Constr` objects representing more complex aspects of the cipher.

This approach to implementing Rijndael-GF bears some similarity to the multivariate quadratic (MQ) systems utilized in *SR*, in that the MQ systems also seek to describe the AES cipher as a system of algebraic equations. Despite this initial similarity though, Rijndael-GF and *SR* are quite different as this implementation seeks to provide a fully generalized algebraic representation of both the whole AES cipher as well as its individual components, while *SR* is instead a family of parameterizable variants of the AES suitable as a framework for comparing different cryptanalytic techniques that can be brought to bear on the AES.

AUTHORS:

- Thomas Gagne (2015-06): initial version

EXAMPLES:

We build Rijndael-GF with a block length of 4 and a key length of 6:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 6)
```

We can encrypt plaintexts and decrypt and ciphertexts by calling the `encrypt` and `decrypt` methods or by calling the Rijndael-GF object explicitly. Note that the default input format is a hex string.

```
sage: plaintext = '00112233445566778899aabbccddeeff'
sage: key = '000102030405060708090a0b0c0d0e0f1011121314151617'
sage: rgf.encrypt(plaintext, key)
```

(continues on next page)

(continued from previous page)

```
'dda97ca4864cdfe06eaf70a0ec0d7191'
sage: rgf.decrypt('dda97ca4864cdfe06eaf70a0ec0d7191', key)
'00112233445566778899aabbccddeeff'
```

We can also use binary strings as input and output.

```
sage: plain = '11101011100111110000000111001100' * 4
sage: key = '01100010111101101000110010111010' * 6
sage: ciphertext = rgf(plain, key, format='binary')
sage: ciphertext
↪ '1101001100001001101011000100001110111011010011001100110011011111100011011100111110011100111100111001110011001100'
↪ '
sage: rgf(ciphertext, key, algorithm='decrypt', format='binary') == plain
True
```

[DR2002] demonstrates an example of encryption which takes the plaintext '3243f6a8885a308d313198a2e0370734' and the key '2b7e151628aed2a6abf7158809cf4f3c' and returns the ciphertext '3902dc1925dc116a8409850b1dfb9732'. We can use this example to demonstrate the correctness of this implementation:

```
sage: rgf = RijndaelGF(4, 4) # change dimensions for this example
sage: plain = '3243f6a8885a308d313198a2e0370734'
sage: key = '2b7e151628aed2a6abf7158809cf4f3c'
sage: expected_ciphertext = '3925841d02dc09fbd118597196a0b32'
sage: rgf.encrypt(plain, key) == expected_ciphertext
True
```

```
sage: rgf = RijndaelGF(4, 6) # revert to previous dimensions
```

To build polynomials representing entries of the output matrix  $B = \phi(A)$  for any round component function  $\phi$ , each of the round component functions (SubBytes, ShiftRows, and MixColumns) have a Round\_Component\_Poly\_Constr object associated with it for building polynomials. These objects can be accessed by calling their getter functions: `rgf.sub_bytes_poly()`, `rgf.shift_rows_poly()`, and `rgf.mix_columns_poly()`. Each returned object has a `__call__` method which takes an index  $i, j$  and an algorithm flag ('encrypt' or 'decrypt') and returns a polynomial representing  $\phi(A)_{i,j}$  in terms of the entries of  $A$ , where  $A$  is an arbitrary state matrix and  $\phi$  is the round component function associated with that particular Round\_Component\_Poly\_Constr object. Some of these objects' `__call__` methods also have additional keywords to modify their behavior, and so we describe the usage of each object below.

`rgf.shift_rows_poly()` and `rgf.mix_columns_poly()` do not have any additional keywords for their `__call__` methods and we can call them as such:

```
sage: sr_pc = rgf.shift_rows_poly_constr()
sage: sr_pc(1, 2)
a13
sage: sr_pc(2, 3, algorithm='decrypt')
a21
```

```
sage: mc_pc = rgf.mix_columns_poly_constr()
sage: mc_pc(1, 2)
a02 + x*a12 + (x + 1)*a22 + a32
sage: mc_pc(2, 3, algorithm='decrypt')
(x^3 + x^2 + 1)*a03 + (x^3 + 1)*a13 + (x^3 + x^2 + x)*a23 + (x^3 + x + 1)*a33
```

`rgf.sub_bytes_poly()` has a single keyword `no_inversion=False`, which when set to `True` returns only the affine transformation step of `SubBytes`. Below describes the usage of `rgf.sub_bytes_poly()`

```
sage: sb_pc = rgf.sub_bytes_poly_constr()
sage: sb_pc(1, 2)
(x^2 + 1)*a12^254 +
(x^3 + 1)*a12^253 +
(x^7 + x^6 + x^5 + x^4 + x^3 + 1)*a12^251 +
(x^5 + x^2 + 1)*a12^247 +
(x^7 + x^6 + x^5 + x^4 + x^2)*a12^239 +
a12^223 +
(x^7 + x^5 + x^4 + x^2 + 1)*a12^191 +
(x^7 + x^3 + x^2 + x + 1)*a12^127 +
(x^6 + x^5 + x + 1)
sage: sb_pc(2, 3, no_inversion=True)
(x^7 + x^3 + x^2 + x + 1)*a23^128 +
(x^7 + x^5 + x^4 + x^2 + 1)*a23^64 +
a23^32 +
(x^7 + x^6 + x^5 + x^4 + x^2)*a23^16 +
(x^5 + x^2 + 1)*a23^8 +
(x^7 + x^6 + x^5 + x^4 + x^3 + 1)*a23^4 +
(x^3 + 1)*a23^2 +
(x^2 + 1)*a23 +
(x^6 + x^5 + x + 1)
```

Because of the order of the affine transformation and the inversion step in `SubBytes`, calling `rgf.sub_bytes_poly()(i, j, algorithm='decrypt')` results in a polynomial with thousands of terms which takes a very long time to compute. Hence, when using the decryption version of `rgf.sub_bytes_poly()` with the intention of evaluating the polynomials it constructs, it is recommended to first call `rgf.sub_bytes_poly()(i, j, algorithm='decrypt', no_inversion=True)` to get a polynomial representing only the inverse affine transformation, evaluate this polynomial for a particular input block, then finally perform the inversion step after the affine transformation polynomial has been evaluated.

```
sage: inv_affine = sb_pc(1, 2, algorithm='decrypt',
.....: no_inversion=True)
sage: state = rgf._hex_to_GF('ff87968431d86a51645151fa773ad009')
sage: evaluated = inv_affine(state.list())
sage: result = evaluated * -1
sage: rgf._GF_to_hex(result)
'79'
```

We can see how the variables of these polynomials are organized in  $A$ :

```
sage: rgf.state_vrs
[a00 a01 a02 a03]
[a10 a11 a12 a13]
[a20 a21 a22 a23]
[a30 a31 a32 a33]
```

The final `Round_Component_Poly_Constr` object we have not discussed yet is `add_round_key_poly`, which corresponds to the `AddRoundKey` round component function. This object differs from the other `Round_Component_Poly_Constr` objects in that it returns polynomials with variables being entries of an input state  $A$  as well as entries of various subkeys. Since there are  $N_r$  subkeys to choose from, `add_round_key_poly` has a keyword of `round=0` to select which subkey to use variables from.

```
sage: ark_pc = rgf.add_round_key_poly_constr()
sage: ark_pc(1, 2)
a12 + k012
sage: ark_pc(1, 2, algorithm='decrypt')
a12 + k012
sage: ark_pc(2, 3, round=7)
a23 + k723
```

We can see how key variables are organized in the original key (the key used to build the rest of the subkeys) below. Note that because key variables are subkey entries, if the key length is longer than the block length we will have entries from multiple subkeys in the original key matrix.

```
sage: rgf.key_vrs
[k000 k001 k002 k003 k100 k101]
[k010 k011 k012 k013 k110 k111]
[k020 k021 k022 k023 k120 k121]
[k030 k031 k032 k033 k130 k131]
```

We can evaluate any of these constructed polynomials for a particular input state (in essence, calculate  $\phi(A)_{i,j}$ ) as such:

```
sage: rgf = RijndaelGF(4, 6)
sage: state = rgf._hex_to_GF('fe7b5170fe7c8e93477f7e4bf6b98071')
sage: poly = mc_pc(3, 2, algorithm='decrypt')
sage: poly(state.list())
x^7 + x^6 + x^5 + x^2 + x
```

We can use the `apply_poly` method to build a matrix whose  $i, j$  th entry equals the polynomial `phi_poly(i, j)` evaluated for a particular input state, where `phi_poly` is the `Round_Component_Poly_Constr` object associated with the round component function  $\phi$ . Essentially, `apply_poly` calculates  $\phi(A)$ , where  $A$  is our input state. Calling `apply_poly` is equivalent to applying the round component function associated this `Round_Component_Poly_Constr` object to  $A$ .

```
sage: state = rgf._hex_to_GF('c4cedcabe694694e4b23bfdd6fb522fa')
sage: result = rgf.apply_poly(state, rgf.sub_bytes_poly_constr())
sage: rgf._GF_to_hex(result)
'1c8b86628e22f92fb32608c1a8d5932d'
sage: result == rgf.sub_bytes(state)
True
```

Alternatively, we can pass a matrix of polynomials as input to `apply_poly`, which will then return another matrix of polynomials. For example, `rgf.state_vrs` can be used as input to make each  $i, j$  th entry of the output matrix equal `phi_poly_constr(i, j)`, where `phi_poly_constr` is our inputted `Round_Component_Poly_Constr` object. This matrix can then be passed through again and so on, demonstrating how one could potentially build a matrix of polynomials representing the entire cipher.

```
sage: state = rgf.apply_poly(rgf.state_vrs, rgf.shift_rows_poly_constr())
sage: state
[a00 a01 a02 a03]
[a11 a12 a13 a10]
[a22 a23 a20 a21]
[a33 a30 a31 a32]
sage: rgf.apply_poly(state, rgf.add_round_key_poly_constr())
[a00 + k000 a01 + k001 a02 + k002 a03 + k003]
```

(continues on next page)

(continued from previous page)

```
[a11 + k010 a12 + k011 a13 + k012 a10 + k013]
[a22 + k020 a23 + k021 a20 + k022 a21 + k023]
[a33 + k030 a30 + k031 a31 + k032 a32 + k033]
```

For any of these `Round_Component_Poly_Constr` objects, we can change the keywords of its `__call__` method when `apply_poly` invokes it by passing `apply_poly` a dictionary mapping keywords to their values.

```
sage: rgf.apply_poly(rgf.state_vrs, rgf.add_round_key_poly_constr(),
.....: poly_constr_attr={'round' : 5})
[a00 + k500 a01 + k501 a02 + k502 a03 + k503]
[a10 + k510 a11 + k511 a12 + k512 a13 + k513]
[a20 + k520 a21 + k521 a22 + k522 a23 + k523]
[a30 + k530 a31 + k531 a32 + k532 a33 + k533]
```

We can build our own `Round_Component_Poly_Constr` objects which correspond to the composition of multiple round component functions with the `compose` method. To do this, if we pass two `Round_Component_Poly_Constr` objects to `compose` where the first object corresponds to the round component function  $f$  and the second to the round component function  $g$ , `compose` will return a new `Round_Component_Poly_Constr` object corresponding to the function  $g \circ f$ . This returned `Round_Component_Poly_Constr` object will have the arguments of `__call__` (`row`, `col`, `algorithm='encrypt'`) and when passed an index  $i, j$  will return  $g(f(A))_{i,j}$  in terms of the entries of  $A$ .

```
sage: rcpc = rgf.compose(rgf.shift_rows_poly_constr(),
.....: rgf.mix_columns_poly_constr())
sage: rcpc
A polynomial constructor of a round component of Rijndael-GF block cipher with block_
↳length 4, key length 6, and 12 rounds.
sage: rcpc(2, 1)
a01 + a12 + x*a23 + (x + 1)*a30

sage: state = rgf._hex_to_GF('afb73eeb1cd1b85162280f27fb20d585')
sage: result = rgf.apply_poly(state, rcpc)
sage: new_state = rgf.shift_rows(state)
sage: new_state = rgf.mix_columns(new_state)
sage: result == new_state
True

sage: rcpc = rgf.compose(rgf.mix_columns_poly_constr(),
.....: rgf.shift_rows_poly_constr())
sage: result = rgf.apply_poly(state, rcpc, algorithm='decrypt')
sage: new_state = rgf.mix_columns(state, algorithm='decrypt')
sage: new_state = rgf.shift_rows(new_state, algorithm='decrypt')
sage: new_state == result
True
```

Alternatively, we can use `compose` to build the polynomial output of a `Round_Component_Poly_Constr` object corresponding to the composition of multiple round functions like above without having to explicitly build our own `Round_Component_Poly_Constr` object. To do this, we simply make the first input a `Round_Component_Poly_Constr` object corresponding to a round component function  $f$  and make the second input a polynomial representing  $g(A)_{i,j}$  for a round component function  $g$ . Given this, `compose` will return a polynomial representing  $g(f(A))_{i,j}$  in terms of the entries of  $A$ .

```
sage: poly = rgf.mix_columns_poly_constr()(0, 3)
sage: poly
```

(continues on next page)

(continued from previous page)

```

x*a03 + (x + 1)*a13 + a23 + a33

(x^7 + x^6 + x^2)*a13^191 +
(x^7 + x^5 + x^4 + x^2 + 1)*a23^191 +
(x^7 + x^5 + x^4 + x^2 + 1)*a33^191 +
(x^2 + 1)*a03^127 +
(x^7 + x^3 + x)*a13^127 +
(x^7 + x^3 + x^2 + x + 1)*a23^127 +
(x^7 + x^3 + x^2 + x + 1)*a33^127 +
(x^6 + x^5 + x + 1)

```

If we use `algorithm='decrypt'` as an argument to `compose`, then the value of `algorithm` will be passed directly to the first argument of `compose` (a `Round_Component_Poly_Constr` object) when it is called, provided the second argument is a polynomial. Setting this flag does nothing if both arguments are `Round_Component_Poly_Constr` objects, since the returned `Round_Component_Poly_Constr` object's `__call__` method must have its own `algorithm` keyword defaulted to 'encrypt'.

```

sage: poly = rgf.shift_rows_poly_constr()(2, 1)
sage: rgf.compose(rgf.mix_columns_poly_constr(), poly, algorithm='decrypt')
(x^3 + x^2 + 1)*a03 + (x^3 + 1)*a13 + (x^3 + x^2 + x)*a23 + (x^3 + x + 1)*a33

sage: state = rgf._hex_to_GF('80121e0776fd1d8a8d8c31bc965d1fee')
sage: with_decrypt = rgf.compose(rgf.sub_bytes_poly_constr(),
....: rgf.shift_rows_poly_constr(), algorithm='decrypt')
sage: result_wd = rgf.apply_poly(state, with_decrypt)
sage: no_decrypt = rgf.compose(rgf.sub_bytes_poly_constr(),
....: rgf.shift_rows_poly_constr())

```

(continues on next page)

(continued from previous page)

```
sage: result_nd = rgf.apply_poly(state, no_decrypt)
sage: result_wd == result_nd
True
```

We can also pass keyword dictionaries of `f_attr` and `g_attr` to `compose` to make `f` and `g` use those keywords during polynomial creation.

```
sage: rcpc = rgf.compose(rgf.add_round_key_poly_constr(),
.....: rgf.add_round_key_poly_constr(),
.....: f_attr={'round' : 4}, g_attr={'round' : 7})
sage: rcpc(1, 2)
a12 + k412 + k712
```

In addition to building polynomial representations of state matrices, we can also build polynomial representations of elements of the expanded key with the `expand_key_poly` method. However, since the key schedule is defined recursively, it is impossible to build polynomials for the key schedule in the same manner as we do for the round component functions. Consequently, `expand_round_key_poly()` is not a `Round_Component_Poly_Constr` object. Instead, `expand_key_poly` is a method which takes an index `i, j` and a round number `round`, and returns a polynomial representing the `i, j` th entry of the `round` th round key. This polynomial's variables are entries of the original key we built above.

```
sage: rgf.expand_key_poly(1, 2, 0)
k012
sage: rgf.expand_key_poly(1, 1, 1)
k111
sage: rgf.expand_key_poly(1, 2, 1)
(x^2 + 1)*k121^254 +
(x^3 + 1)*k121^253 +
(x^7 + x^6 + x^5 + x^4 + x^3 + 1)*k121^251 +
(x^5 + x^2 + 1)*k121^247 +
(x^7 + x^6 + x^5 + x^4 + x^2)*k121^239 +
k121^223 +
(x^7 + x^5 + x^4 + x^2 + 1)*k121^191 +
(x^7 + x^3 + x^2 + x + 1)*k121^127 +
k010 +
(x^6 + x^5 + x)
```

Since `expand_key_poly` is not actually a `Round_Component_Poly_Constr` object, we cannot use it as input to `apply_poly` or `compose`.

```
sage: rgf.apply_poly(state, rgf.expand_key_poly)
Traceback (most recent call last):
...
TypeError: keyword 'poly_constr' must be a Round_Component_Poly_Constr
sage: rgf.compose(rgf.expand_key_poly, rgf.sub_bytes_poly_constr())
Traceback (most recent call last):
...
TypeError: keyword 'f' must be a Round_Component_Poly_Constr
```

```
class sage.crypto.mq.rijndael_gf.RijndaelGF(Nb, Nk, state_chr='a', key_chr='k')
```

Bases: `SageObject`

An algebraically generalized version of the AES cipher.

INPUT:

- `Nb` – The block length of this instantiation. Must be between 4 and 8.
- `Nk` – The key length of this instantiation. Must be between 4 and 8.
- `state_chr` – The variable name for polynomials representing elements from state matrices.
- `key_chr` – The variable name for polynomials representing elements of the key schedule.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(6, 8)
sage: rgf
Rijndael-GF block cipher with block length 6, key length 8, and 14 rounds.
```

By changing `state_chr` we can alter the names of variables in polynomials representing elements from state matrices.

```
sage: rgf = RijndaelGF(4, 6, state_chr='myChr')
sage: rgf.mix_columns_poly_constr()(3, 2)
(x + 1)*myChr02 + myChr12 + myChr22 + x*myChr32
```

We can also alter the name of variables in polynomials representing elements from round keys by changing `key_chr`.

```
sage: rgf = RijndaelGF(4, 6, key_chr='myKeyChr')
sage: rgf.expand_key_poly(1, 2, 1)
(x^2 + 1)*myKeyChr121^254 +
(x^3 + 1)*myKeyChr121^253 +
(x^7 + x^6 + x^5 + x^4 + x^3 + 1)*myKeyChr121^251 +
(x^5 + x^2 + 1)*myKeyChr121^247 +
(x^7 + x^6 + x^5 + x^4 + x^2)*myKeyChr121^239 +
myKeyChr121^223 +
(x^7 + x^5 + x^4 + x^2 + 1)*myKeyChr121^191 +
(x^7 + x^3 + x^2 + x + 1)*myKeyChr121^127 +
myKeyChr010 +
(x^6 + x^5 + x)
```

**class Round\_Component\_Poly\_Constr**(*polynomial\_constr*, *rgf*, *round\_component\_name=None*)

Bases: `SageObject`

An object which constructs polynomials representing round component functions of a `RijndaelGF` object.

INPUT:

- `polynomial_constr` – A function which takes an index `row`, `col` and returns a polynomial representing the `row`, `col` th entry of a matrix after a specific round component function has been applied to it. This polynomial must be in terms of entries of the input matrix to that round component function and of entries of various subkeys. `polynomial_constr` must have arguments of the form `polynomial_constr(row, col, algorithm='encrypt', **kwargs)` and must be able to be called as `polynomial_constr(row, col)`.
- `rgf` – The `RijndaelGF` object whose state entries are represented by polynomials returned from `polynomial_constr`.
- `round_component_name` – The name of the round component function this object corresponds to as a string. Used solely for display purposes.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import \
.....: RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: rcpc = RijndaelGF.Round_Component_Poly_Constr(
.....: rgf._shift_rows_pc, rgf, "Shift Rows")
sage: rcpc
A polynomial constructor for the function 'Shift Rows' of Rijndael-GF block_
↳ cipher with block length 4, key length 4, and 10 rounds.
```

If  $\phi$  is the round component function to which this object corresponds to, then  $\_\_call\_\_(i, j) = \phi(A)_{i,j}$ , where  $A$  is an arbitrary input matrix. Note that the polynomial returned by  $\_\_call\_\_(i, j)$  will be in terms of the entries of  $A$ .

```
sage: rcpc = RijndaelGF.Round_Component_Poly_Constr(
.....: rgf._mix_columns_pc, rgf, "Mix Columns")
sage: poly = rcpc(1, 2); poly
a02 + x*a12 + (x + 1)*a22 + a32
sage: state = rgf._hex_to_GF('d1876c0f79c4300ab45594add66ff41f')
sage: result = rgf.mix_columns(state)
sage: result[1,2] == poly(state.list())
True
```

Invoking this objects  $\_\_call\_\_$  method passes its arguments directly to `polynomial_constr` and returns the result. In a sense, `Round_Component_Poly_Constr` acts as a wrapper for the `polynomial_constr` method and helps ensure that each `Round_Component_Poly_Constr` object will act similarly.

```
sage: all(rgf._mix_columns_pc(i, j) == rcpc(i, j)
.....: for i in range(4) for j in range(4))
True
```

Since all keyword arguments of `polynomial_constr` must have a default value except for `row` and `col`, we can always call a `Round_Component_Poly_Constr` object by  $\_\_call\_\_(row, col)$ . Because of this, methods such as `apply_poly` and `compose` will only call  $\_\_call\_\_(row, col)$  when passed a `Round_Component_Poly_Constr` object. In order to change this object's behavior and force methods such as `apply_poly` to use non-default values for keywords we can pass dictionaries mapping keywords to non-default values as input to `apply_poly` and `compose`.

```
sage: rgf.apply_poly(rgf.state_vrs,
.....: rgf.add_round_key_poly_constr(),
.....: poly_constr_attr={'round' : 9})
[a00 + k900 a01 + k901 a02 + k902 a03 + k903]
[a10 + k910 a11 + k911 a12 + k912 a13 + k913]
[a20 + k920 a21 + k921 a22 + k922 a23 + k923]
[a30 + k930 a31 + k931 a32 + k932 a33 + k933]
```

```
sage: fn = rgf.compose(rgf.add_round_key_poly_constr(),
.....: rgf.add_round_key_poly_constr(),
.....: f_attr={'round' : 3}, g_attr={'round' : 7})
sage: fn(2, 3)
a23 + k323 + k723
```

Because all `Round_Component_Poly_Constr` objects are callable as  $\_\_call\_\_(row, col, algorithm)$ ,  $\_\_call\_\_$  will check the validity of these three arguments automatically. Any other

keywords, however, must be checked in `polynomial_constr`.

```
sage: def my_poly_constr(row, col, algorithm='encrypt'):
....:     return x * rgf._F.one() # example body with no checks
sage: rcpc = RijndaelGF.Round_Component_Poly_Constr(
....: my_poly_constr, rgf, "My Poly Constr")
sage: rcpc(-1, 2)
Traceback (most recent call last):
...
ValueError: keyword 'row' must be in range 0 - 3
sage: rcpc(1, 2, algorithm=5)
Traceback (most recent call last):
...
ValueError: keyword 'algorithm' must be either 'encrypt' or 'decrypt'
```

### `add_round_key(state, round_key)`

Return the round-key addition of matrices `state` and `round_key`.

INPUT:

- `state` – The state matrix to have `round_key` added to.
- `round_key` – The round key to add to `state`.

OUTPUT:

- A state matrix which is the round key addition of `state` and `round_key`. This transformation is simply the entrywise addition of these two matrices.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: state = rgf._hex_to_GF('36339d50f9b539269f2c092dc4406d23')
sage: key = rgf._hex_to_GF('7CC78D0E22754E667E24573F454A6531')
sage: key_schedule = rgf.expand_key(key)
sage: result = rgf.add_round_key(state, key_schedule[0])
sage: rgf._GF_to_hex(result)
'4af4105edbc07740e1085e12810a0812'
```

### `add_round_key_poly_constr()`

Return the `Round_Component_Poly_Constr` object corresponding to `AddRoundKey`.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: ark_pc = rgf.add_round_key_poly_constr()
sage: ark_pc
A polynomial constructor for the function 'Add Round Key' of Rijndael-GF block_
↪ cipher with block length 4, key length 4, and 10 rounds.
sage: ark_pc(0, 1)
a01 + k001
```

When invoking the returned object's `__call__` method, changing the value of `algorithm='encrypt'` does nothing, since the `AddRoundKey` round component function is its own inverse.

```
sage: with_encrypt = ark_pc(1, 1, algorithm='encrypt')
sage: with_decrypt = ark_pc(1, 1, algorithm='decrypt')
sage: with_encrypt == with_decrypt
True
```

When invoking the returned object's `__call__` method, one can change the round subkey used in the returned polynomial by changing the `round=0` keyword.

```
sage: ark_pc(2, 1, round=7)
a21 + k721
```

When passing the returned object to methods such as `apply_poly` and `compose`, we can make these methods use a non-default value for `round=0` by passing in a dictionary mapping `round` to a different value.

```
sage: rgf.apply_poly(rgf.state_vrs, ark_pc,
....: poly_constr_attr={'round' : 6})
[a00 + k600 a01 + k601 a02 + k602 a03 + k603]
[a10 + k610 a11 + k611 a12 + k612 a13 + k613]
[a20 + k620 a21 + k621 a22 + k622 a23 + k623]
[a30 + k630 a31 + k631 a32 + k632 a33 + k633]
```

```
sage: rcpc = rgf.compose(ark_pc, ark_pc,
....: f_attr={'round' : 3}, g_attr={'round' : 5})
sage: rcpc(3, 1)
a31 + k331 + k531
```

**apply\_poly**(*state*, *poly\_constr*, *algorithm*='encrypt', *keys*=None, *poly\_constr\_attr*=None)

Return a state matrix where `poly_method` is applied to each entry.

INPUT:

- `state` – The state matrix over  $\mathbb{F}_{2^8}$  to which `poly_method` is applied to.
- `poly_constr` – The `Round_Component_Poly_Constr` object to build polynomials during evaluation.
- `algorithm` – (default: “encrypt”) Passed directly to `rcpc` to select encryption or decryption. The encryption flag is “encrypt” and the decrypt flag is “decrypt”.
- `keys` – (default: None) An array of  $N_r$  subkey matrices to replace any key variables in any polynomials returned by `poly_method`. Must be identical to the format returned by `expand_key`. If any polynomials have key variables and `keys` is not supplied, the key variables will remain as-is.
- `poly_constr_attr` – (default:None) A dictionary of keyword attributes to pass to `rcpc` when it is called.

OUTPUT:

- A state matrix in  $\mathbb{F}_{2^8}$  whose  $i, j$  th entry equals the polynomial `poly_constr(i, j, algorithm, **poly_constr_attr)` evaluated by setting its variables equal to the corresponding entries of `state`.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: state = rgf._hex_to_GF('3b59cb73fcd90ee05774222dc067fb68')
sage: result = rgf.apply_poly(state, rgf.shift_rows_poly_constr())
```

(continues on next page)

(continued from previous page)

```
sage: rgf._GF_to_hex(result)
'3bd92268fc74fb735767cbe0c0590e2d'
```

Calling `apply_poly` with the `Round_Component_Poly_Constr` object of a round component (e.g. `sub_bytes_poly`) is identical to calling that round component function itself.

```
sage: state = rgf._hex_to_GF('4915598f55e5d7a0daca94fa1f0a63f7')
sage: apply_poly_result = rgf.apply_poly(state,
.....: rgf.sub_bytes_poly_constr())
sage: direct_result = rgf.sub_bytes(state)
sage: direct_result == apply_poly_result
True
```

If the `Round_Component_Poly_Constr` object's `__call__` method returns a polynomial with state variables as well as key variables, we can supply a list of  $N_r$  round keys `keys` whose elements are evaluated as the key variables. If this is not provided, the key variables will remain as is.:

```
sage: state = rgf._hex_to_GF('14f9701ae35fe28c440adf4d4ea9c026')
sage: key = rgf._hex_to_GF('54d990a16ba09ab596bbf40ea111702f')
sage: keys = rgf.expand_key(key)
sage: result = rgf.apply_poly(state,
.....: rgf.add_round_key_poly_constr(), keys=keys)
sage: result == rgf.add_round_key(state, key)
True

sage: rgf.apply_poly(state, rgf.add_round_key_poly_constr())[0,0]
k000 + (x^4 + x^2)
```

We can change the value of the keywords of `poly_constr`'s `__call__` method when `apply_poly` calls it by passing in a dictionary `poly_constr_attr` mapping keywords to their values.

```
sage: rgf.apply_poly(rgf.state_vrs,
.....: rgf.add_round_key_poly_constr(),
.....: poly_constr_attr={'round' : 5})
[a00 + k500 a01 + k501 a02 + k502 a03 + k503]
[a10 + k510 a11 + k511 a12 + k512 a13 + k513]
[a20 + k520 a21 + k521 a22 + k522 a23 + k523]
[a30 + k530 a31 + k531 a32 + k532 a33 + k533]
```

### `block_length()`

Return the block length of this instantiation of Rijndael-GF.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 6)
sage: rgf.block_length()
4
```

### `compose(f, g, algorithm='encrypt', f_attr=None, g_attr=None)`

Return a `Round_Component_Poly_Constr` object corresponding to  $g \circ f$  or the polynomial output of this object's `__call__` method.

INPUT:

- `f` – A `Round_Component_Poly_Constr` object corresponding to a round component function  $f$ .
- `g` – A `Round_Component_Poly_Constr` object corresponding to a round component function  $g$  or a polynomial output of this object's `__call__` method.
- `algorithm` – (default: “encrypt”) Whether `f` and `g` should use their encryption transformations or their decryption transformations. Does nothing if `g` is a `Round_Component_Poly_Constr` object. The encryption flag is “encrypt” and the decryption flag is “decrypt”.
- `f_attr` – (default: None) A dictionary of keyword attributes to pass to `f` when it is called.
- `g_attr` – (default: None) A dictionary of keyword attributes to pass to `g` when it is called. Does nothing if `g` is a polynomial.

OUTPUT:

- If `g` is a `Round_Component_Poly_Constr` object corresponding to a round component function  $g$ , then `compose` returns a `Round_Component_Poly_Constr` corresponding to the round component function  $g \circ f$ , where  $f$  is the round component function corresponding to the first argument `f`. On the other hand, if  $g = g(A)_{i,j}$  for a round component function  $g$ , then `compose` returns  $g(f(A))_{i,j}$ , where  $A$  is an arbitrary input state matrix.

EXAMPLES:

This function allows us to determine the polynomial representations of entries across multiple round functions. For example, if we wanted a polynomial representing the 1,3 entry of a matrix after we first apply `ShiftRows` and then `MixColumns` to that matrix, we do:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: mcp = rgf.mix_columns_poly_constr()(1, 3); mcp
a03 + x*a13 + (x + 1)*a23 + a33
sage: result = rgf.compose(rgf.shift_rows_poly_constr(), mcp)
sage: result
a03 + x*a10 + (x + 1)*a21 + a32
```

We can test the correctness of this:

```
sage: state = rgf._hex_to_GF('fa636a2825b339c940668a3157244d17')
sage: new_state = rgf.shift_rows(state)
sage: new_state = rgf.mix_columns(new_state)
sage: result(state.list()) == new_state[1,3]
True
```

We can also use `compose` to build a new `Round_Component_Poly_Constr` object corresponding to the composition of multiple round functions as such:

```
sage: fn = rgf.compose(rgf.shift_rows_poly_constr(),
....: rgf.mix_columns_poly_constr())
sage: fn(1, 3)
a03 + x*a10 + (x + 1)*a21 + a32
```

If we use `compose` to make a new `Round_Component_Poly_Constr` object, we can use that object as input to `apply_poly` and `compose`:

```
sage: state = rgf._hex_to_GF('36400926f9336d2d9fb59d23c42c3950')
sage: result = rgf.apply_poly(state, fn)
sage: rgf._GF_to_hex(result)
```

(continues on next page)

(continued from previous page)

```
'f4bcd45432e554d075f1d6c51dd03b3c'
sage: new_state = rgf.shift_rows(state)
sage: new_state = rgf.mix_columns(new_state)
sage: result == new_state
True
```

```
sage: fn2 = rgf.compose(rgf.sub_bytes_poly_constr(), fn)
```

If the second argument is a polynomial, then the value of `algorithm` is passed directly to the first argument `f` during evaluation. However, if the second argument is a `Round_Component_Poly_Constr` object, changing `algorithm` does nothing since the returned object has its own `algorithm='encrypt'` keyword.

```
sage: f = rgf.compose(rgf.sub_bytes_poly_constr(),
....: rgf.mix_columns_poly_constr(), algorithm='decrypt')
sage: g = rgf.compose(rgf.sub_bytes_poly_constr(),
....: rgf.mix_columns_poly_constr())
sage: all(f(i,j) == g(i,j) for i in range(4) for j in range(4))
True
```

We can change the keyword attributes of the `__call__` methods of `f` and `g` by passing dictionaries `f_attr` and `g_attr` to `compose`.

```
sage: fn = rgf.compose(rgf.add_round_key_poly_constr(),
....: rgf.add_round_key_poly_constr(),
....: f_attr={'round' : 4}, g_attr={'round' : 7})
sage: fn(1, 2)
a12 + k412 + k712
```

**decrypt**(*ciphertext*, *key*, *format='hex'*)

Return the ciphertext `ciphertext` decrypted with the key `key`.

INPUT:

- `ciphertext` – The ciphertext to be decrypted.
- `key` – The key to decrypt ciphertext with.
- `format` – (default: `hex`) The string format that both `ciphertext` and `key` must be in, either “hex” or “binary”.

OUTPUT:

- A string in the format `format` of ciphertext decrypted with key `key`.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: key = '2dfb02343f6d12dd09337ec75b36e3f0'
sage: ciphertext = '54d990a16ba09ab596bbf40ea111702f'
sage: expected_plaintext = '1e1d913b7274ad9b5a4ab1a5f9133b93'
sage: rgf.decrypt(ciphertext, key) == expected_plaintext
True
```

We can also decrypt messages using binary strings.

```

sage: key = '00011010000011100011000000111101' * 4
sage: ciphertext = '00110010001110000111110110000001' * 4
sage: expected_plaintext = ('10111111010011100111100101010100111'
.....: '111101000010110110000110100000000000000010000000100111011'
.....: '0100001111100011010001101101001011')
sage: result = rgf.decrypt(ciphertext, key, format='binary')
sage: result == expected_plaintext
True

```

**encrypt**(*plain*, *key*, *format*='hex')

Return the plaintext *plain* encrypted with the key *key*.

INPUT:

- *plain* – The plaintext to be encrypted.
- *key* – The key to encrypt *plain* with.
- *format* – (default: hex) The string format of *key* and *plain*, either “hex” or “binary”.

OUTPUT:

- A string of the plaintext *plain* encrypted with the key *key*.

EXAMPLES:

```

sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: key = 'c81677bc9b7ac93b25027992b0261996'
sage: plain = 'fde3bad205e5d0d73547964ef1fe37f1'
sage: expected_ciphertext = 'e767290ddfc6414e3c50a444bec081f0'
sage: rgf.encrypt(plain, key) == expected_ciphertext
True

```

We can encrypt binary strings as well.

```

sage: key = '10010111110000011111011011010001' * 4
sage: plain = '00000000101000000000000001111011' * 4
sage: expected_ciphertext = ('11010111100100001010001011110010111'
.....: '111001100000001111110010001101110010100000001000111000010'
.....: '00100111011011001000111101111110100')
sage: result = rgf.encrypt(plain, key, format='binary')
sage: result == expected_ciphertext
True

```

**expand\_key**(*key*)

Return the expanded key schedule from *key*.

INPUT:

- *key* – The key to build a key schedule from. Must be a matrix over  $\mathbf{F}_{2^8}$  of dimensions  $4 \times N_k$ .

OUTPUT:

- A length  $Nr$  list of  $4 \times N_b$  matrices corresponding to the expanded key. The  $n$ th entry of the list corresponds to the matrix used in the `add_round_key` step of the  $n$ th round.

EXAMPLES:

```

sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 6)
sage: key = '331D0084B176C3FB59CAA0EDA271B565BB5D9A2D1E4B2892'
sage: key_state = rgf._hex_to_GF(key)
sage: key_schedule = rgf.expand_key(key_state)
sage: rgf._GF_to_hex(key_schedule[0])
'331d0084b176c3fb59caa0eda271b565'
sage: rgf._GF_to_hex(key_schedule[6])
'5c5d51c4121f018d0f4f3e408ae9f78c'

```

**expand\_key\_poly**(row, col, round)

Return a polynomial representing the row, col th entry of the round th round key.

INPUT:

- row – The row position of the element represented by this polynomial.
- col – The column position of the element represented by this polynomial.

OUTPUT:

- A polynomial representing the row, col th entry of the round th round key in terms of entries of the input key.

EXAMPLES:

```

sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: rgf.expand_key_poly(1, 2, 0)
k012
sage: rgf.expand_key_poly(1, 2, 1)
(x^2 + 1)*k023^254 +
(x^3 + 1)*k023^253 +
(x^7 + x^6 + x^5 + x^4 + x^3 + 1)*k023^251 +
(x^5 + x^2 + 1)*k023^247 +
(x^7 + x^6 + x^5 + x^4 + x^2)*k023^239 +
k023^223 +
(x^7 + x^5 + x^4 + x^2 + 1)*k023^191 +
(x^7 + x^3 + x^2 + x + 1)*k023^127 +
k010 +
k011 +
k012 +
(x^6 + x^5 + x)

```

It should be noted that `expand_key_poly` cannot be used with `apply_poly` or `compose`, since `expand_key_poly` is not a `Round_Component_Poly_Constr` object.

```

sage: rgf.compose(rgf.sub_bytes_poly_constr(), rgf.expand_key_poly)
Traceback (most recent call last):
...
TypeError: keyword 'g' must be a Round_Component_Poly_Constr or a polynomial_
↳ over Finite Field in x of size 2^8
sage: state = rgf._hex_to_GF('00000000000000000000000000000000')
sage: rgf.apply_poly(state, rgf.expand_key_poly)
Traceback (most recent call last):

```

(continues on next page)

(continued from previous page)

```
...
TypeError: keyword 'poly_constr' must be a Round_Component_Poly_Constr
```

**key\_length()**

Return the key length of this instantiation of Rijndael-GF.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 8)
sage: rgf.key_length()
8
```

**mix\_columns(state, algorithm='encrypt')**

Return the application of MixColumns to the state matrix state.

INPUT:

- state – The state matrix to apply MixColumns to.
- algorithm – (default: “encrypt”) Whether to perform the encryption version of MixColumns, or its decryption inverse. The encryption flag is “encrypt” and the decryption flag is “decrypt”.

OUTPUT:

- The state matrix over  $\mathbb{F}_{2^8}$  which is the result of applying MixColumns to state.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: state = rgf._hex_to_GF('cd54c7283864c0c55d4c727e90c9a465')
sage: result = rgf.mix_columns(state)
sage: rgf._GF_to_hex(result)
'921f748fd96e937d622d7725ba8ba50c'
sage: decryption = rgf.mix_columns(result, algorithm='decrypt')
sage: decryption == state
True
```

**mix\_columns\_poly\_constr()**

Return a Round\_Component\_Poly\_Constr object corresponding to MixColumns.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: mc_pc = rgf.mix_columns_poly_constr()
sage: mc_pc
A polynomial constructor for the function 'Mix Columns' of Rijndael-GF block_
↪ cipher with block length 4, key length 4, and 10 rounds.
sage: mc_pc(1, 2)
a02 + x*a12 + (x + 1)*a22 + a32
sage: mc_pc(1, 0, algorithm='decrypt')
(x^3 + 1)*a00 + (x^3 + x^2 + x)*a10 + (x^3 + x + 1)*a20 + (x^3 + x^2 + 1)*a30
```

The returned object’s `__call__` method has no additional keywords, unlike `sub_bytes_poly_constr()` and `add_round_key_poly_constr()`.

**number\_rounds()**

Return the number of rounds used in this instantiation of Rijndael-GF.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(5, 4)
sage: rgf.number_rounds()
11
```

**shift\_rows(*state*, *algorithm*='encrypt')**

Return the application of ShiftRows to the state matrix *state*.

INPUT:

- *state* – A state matrix over  $F_{2^8}$  to which ShiftRows is applied to.
- *algorithm* – (default: “encrypt”) Whether to perform the encryption version of ShiftRows or its decryption inverse. The encryption flag is “encrypt” and the decryption flag is “decrypt”.

OUTPUT:

- A state matrix over  $F_{2^8}$  which is the application of ShiftRows to *state*.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: state = rgf._hex_to_GF('adcb0f257e9c63e0bc557e951c15ef01')
sage: result = rgf.shift_rows(state)
sage: rgf._GF_to_hex(result)
'ad9c7e017e55ef25bc150fe01ccb6395'
sage: decryption = rgf.shift_rows(result, algorithm='decrypt')
sage: decryption == state
True
```

**shift\_rows\_poly\_constr()**

Return a Round\_Component\_Poly\_Constr object corresponding to ShiftRows.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: sr_pc = rgf.shift_rows_poly_constr()
sage: sr_pc(3, 0)
a33
sage: sr_pc(2, 1, algorithm='decrypt')
a23
```

The returned object’s `__call__` method has no additional keywords, unlike `sub_bytes_poly_constr()` and `add_round_key_poly_constr`.

**sub\_bytes(*state*, *algorithm*='encrypt')**

Return the application of SubBytes to the state matrix *state*.

INPUT:

- *state* – The state matrix to apply SubBytes to.

- `algorithm` – (default: “encrypt”) Whether to apply the encryption step of SubBytes or its decryption inverse. The encryption flag is “encrypt” and the decryption flag is “decrypt”.

OUTPUT:

- The state matrix over  $F_{2^8}$  where SubBytes has been applied to every entry of state.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: state = rgf._hex_to_GF('d1c4941f7955f40fb46f6c0ad68730ad')
sage: result = rgf.sub_bytes(state)
sage: rgf._GF_to_hex(result)
'3e1c22c0b6fcbf768da85067f6170495'
sage: decryption = rgf.sub_bytes(result, algorithm='decrypt')
sage: decryption == state
True
```

### `sub_bytes_poly_constr()`

Return the Round\_Component\_Poly\_Constr object corresponding to SubBytes.

EXAMPLES:

```
sage: from sage.crypto.mq.rijndael_gf import RijndaelGF
sage: rgf = RijndaelGF(4, 4)
sage: sb_pc = rgf.sub_bytes_poly_constr()
sage: sb_pc
A polynomial constructor for the function 'SubBytes' of Rijndael-GF block_
↳ cipher with block length 4, key length 4, and 10 rounds.
sage: sb_pc(2, 3)
(x^2 + 1)*a23^254 +
(x^3 + 1)*a23^253 +
(x^7 + x^6 + x^5 + x^4 + x^3 + 1)*a23^251 +
(x^5 + x^2 + 1)*a23^247 +
(x^7 + x^6 + x^5 + x^4 + x^2)*a23^239 +
a23^223 +
(x^7 + x^5 + x^4 + x^2 + 1)*a23^191 +
(x^7 + x^3 + x^2 + x + 1)*a23^127 +
(x^6 + x^5 + x + 1)
```

The returned object’s `__call__` method has an additional keyword of `no_inversion=False`, which causes the returned polynomial to represent only the affine transformation step of SubBytes.

```
sage: sb_pc(1, 0, no_inversion=True)
(x^7 + x^3 + x^2 + x + 1)*a10^128 +
(x^7 + x^5 + x^4 + x^2 + 1)*a10^64 +
a10^32 +
(x^7 + x^6 + x^5 + x^4 + x^2)*a10^16 +
(x^5 + x^2 + 1)*a10^8 +
(x^7 + x^6 + x^5 + x^4 + x^3 + 1)*a10^4 +
(x^3 + 1)*a10^2 +
(x^2 + 1)*a10 +
(x^6 + x^5 + x + 1)
```

We can build a polynomial representing the inverse transformation by setting the keyword

`algorithm='decrypt'`. However, the order of the affine transformation and the inversion step in Sub-Bytes means that this polynomial has thousands of terms and is very slow to compute. Hence, if one wishes to build the decryption polynomial with the intention of evaluating that polynomial for a particular input, it is strongly recommended to first call `sb_pc(i, j, algorithm='decrypt', no_inversion=True)` to build a polynomial representing only the inverse affine transformation, evaluate this polynomial for your intended input, then finally calculate the inverse of the result.

```
sage: poly = sb_pc(1, 2, algorithm='decrypt', no_inversion=True)
sage: state = rgf._hex_to_GF('39daee38f4f1a82aaf432410c36d45b9')
sage: result = poly(state.list())
sage: rgf._GF_to_hex(result * -1)
'49'
```

When passing the returned object to `apply_poly` and `compose`, we can make those methods change the keyword `no_inversion` of this object's `__call__` method by passing the dictionary `{'no_inversion' : True}` to them.

```
sage: result = rgf.apply_poly(state, sb_pc,
....: poly_constr_attr={'no_inversion' : True})
sage: rgf._GF_to_hex(result)
'961c72894526f746aa85fc920adcc719'
```

```
sage: rcpc = rgf.compose(sb_pc, rgf.shift_rows_poly_constr(),
....: f_attr={'no_inversion' : True})
```

Note that if we set `algorithm='decrypt'` for `apply_poly`, it will perform the necessary performance enhancement described above automatically. The structure of `compose`, however, unfortunately does not allow this enhancement to be employed.

## HARD LATTICE GENERATOR

This module contains lattice related functions relevant in cryptography.

Feel free to add more functionality.

AUTHORS:

- Richard Lindner <[rlindner@cdc.informatik.tu-darmstadt.de](mailto:rlindner@cdc.informatik.tu-darmstadt.de)>
- Michael Schneider <[mischnei@cdc.informatik.tu-darmstadt.de](mailto:mischnei@cdc.informatik.tu-darmstadt.de)>

```
sage.crypto.lattice.gen_lattice(type='modular', n=4, m=8, q=11, seed=None, quotient=None,
                                dual=False, ntl=False, lattice=False)
```

This function generates different types of integral lattice bases of row vectors relevant in cryptography.

Randomness can be set either with `seed`, or by using `sage.misc.randstate.set_random_seed()`.

INPUT:

- **type** – one of the following strings
  - 'modular' (default) – A class of lattices for which asymptotic worst-case to average-case connections hold. For more refer to [Aj1996].
  - 'random' – Special case of modular (n=1). A dense class of lattice used for testing basis reduction algorithms proposed by Goldstein and Mayer [GM2002].
  - 'ideal' – Special case of modular. Allows for a more compact representation proposed by [LM2006].
  - 'cyclotomic' – Special case of ideal. Allows for efficient processing proposed by [LM2006].
- **n** – Determinant size, primal:  $\det(L) = q^n$ , dual:  $\det(L) = q^{m-n}$ . For ideal lattices this is also the degree of the quotient polynomial.
- **m** – Lattice dimension,  $L \subseteq Z^m$ .
- **q** – Coefficient size,  $q - Z^m \subseteq L$ .
- **seed** – Randomness seed.
- **quotient** – For the type ideal, this determines the quotient polynomial. Ignored for all other types.
- **dual** – Set this flag if you want a basis for  $q - \text{dual}(L)$ , for example for Regev's LWE bases [Reg2005].
- **ntl** – Set this flag if you want the lattice basis in NTL readable format.
- **lattice** – Set this flag if you want a `FreeModule_submodule_with_basis_integer` object instead of an integer matrix representing the basis.

OUTPUT:

B a unique size-reduced triangular (primal: lower\_left, dual: lower\_right) basis of row vectors for the lattice in question.

EXAMPLES:

Modular basis:

```
sage: sage.crypto.gen_lattice(m=10, seed=42)
[11  0  0  0  0  0  0  0  0  0]
[ 0 11  0  0  0  0  0  0  0  0]
[ 0  0 11  0  0  0  0  0  0  0]
[ 0  0  0 11  0  0  0  0  0  0]
[ 2  4  3  5  1  0  0  0  0  0]
[ 1 -5 -4  2  0  1  0  0  0  0]
[-4  3 -1  1  0  0  1  0  0  0]
[-2 -3 -4 -1  0  0  0  1  0  0]
[-5 -5  3  3  0  0  0  0  1  0]
[-4 -3  2 -5  0  0  0  0  0  1]
```

Random basis:

```
sage: sage.crypto.gen_lattice(type='random', n=1, m=10, q=11^4, seed=42)
[14641  0  0  0  0  0  0  0  0  0]
[  431  1  0  0  0  0  0  0  0  0]
[-4792  0  1  0  0  0  0  0  0  0]
[ 1015  0  0  1  0  0  0  0  0  0]
[-3086  0  0  0  1  0  0  0  0  0]
[-5378  0  0  0  0  1  0  0  0  0]
[  4769  0  0  0  0  0  1  0  0  0]
[-1159  0  0  0  0  0  0  1  0  0]
[  3082  0  0  0  0  0  0  0  1  0]
[-4580  0  0  0  0  0  0  0  0  1]
```

Ideal bases with quotient  $x^n-1$ ,  $m=2*n$  are NTRU bases:

```
sage: sage.crypto.gen_lattice(type='ideal', seed=42, quotient=x^4-1)
[11  0  0  0  0  0  0  0]
[ 0 11  0  0  0  0  0  0]
[ 0  0 11  0  0  0  0  0]
[ 0  0  0 11  0  0  0  0]
[-2 -3 -3  4  1  0  0  0]
[ 4 -2 -3 -3  0  1  0  0]
[-3  4 -2 -3  0  0  1  0]
[-3 -3  4 -2  0  0  0  1]
```

Ideal bases also work with polynomials:

```
sage: R.<t> = PolynomialRing(ZZ)
sage: sage.crypto.gen_lattice(type='ideal', seed=1234, quotient=t^4-1)
[11  0  0  0  0  0  0  0]
[ 0 11  0  0  0  0  0  0]
[ 0  0 11  0  0  0  0  0]
[ 0  0  0 11  0  0  0  0]
```

(continues on next page)

(continued from previous page)

```
[ 1  4 -3  3  1  0  0  0]
[ 3  1  4 -3  0  1  0  0]
[-3  3  1  4  0  0  1  0]
[ 4 -3  3  1  0  0  0  1]
```

Cyclotomic bases with  $n=2^k$  are SWIFFT bases:

```
sage: sage.crypto.gen_lattice(type='cyclotomic', seed=42)
[11  0  0  0  0  0  0  0]
[ 0 11  0  0  0  0  0  0]
[ 0  0 11  0  0  0  0  0]
[ 0  0  0 11  0  0  0  0]
[-2 -3 -3  4  1  0  0  0]
[-4 -2 -3 -3  0  1  0  0]
[ 3 -4 -2 -3  0  0  1  0]
[ 3  3 -4 -2  0  0  0  1]
```

Dual modular bases are related to Regev's famous public-key encryption [Reg2005]:

```
sage: sage.crypto.gen_lattice(type='modular', m=10, seed=42, dual=True)
[ 0  0  0  0  0  0  0  0  0 11]
[ 0  0  0  0  0  0  0  0  0 11  0]
[ 0  0  0  0  0  0  0  0 11  0  0]
[ 0  0  0  0  0  0 11  0  0  0  0]
[ 0  0  0  0  0 11  0  0  0  0  0]
[ 0  0  0  0 11  0  0  0  0  0  0]
[ 0  0  0  1 -5 -2 -1  1 -3  5]
[ 0  0  1  0 -3  4  1  4 -3 -2]
[ 0  1  0  0 -4  5 -3  3  5  3]
[ 1  0  0  0 -2 -1  4  2  5  4]
```

Relation of primal and dual bases:

```
sage: B_primal=sage.crypto.gen_lattice(m=10, q=11, seed=42)
sage: B_dual=sage.crypto.gen_lattice(m=10, q=11, seed=42, dual=True)
sage: B_dual_alt=transpose(11*B_primal.inverse()).change_ring(ZZ)
sage: B_dual_alt.hermite_form() == B_dual.hermite_form()
True
```

## (RING-)LWE ORACLE GENERATORS

The Learning with Errors problem (LWE) is solving linear systems of equations where the right hand side has been disturbed ‘slightly’ where ‘slightly’ is made precise by a noise distribution - typically a discrete Gaussian distribution. See [Reg09] for details.

The Ring Learning with Errors problem (LWE) is solving a set of univariate polynomial equations - typically in a cyclotomic field - where the right hand side was disturbed ‘slightly’. See [LPR2010] for details.

This module implements generators of LWE samples where parameters are chosen following proposals in the cryptographic literature.

EXAMPLES:

We get 30 samples from an LWE oracle parameterised by security parameter  $n=20$  and where the modulus and the standard deviation of the noise are chosen as in [Reg09]:

```
sage: from sage.crypto.lwe import samples
sage: S = samples(30, 20, 'Regev')
sage: len(S)
30
sage: S[0][0].parent(), S[0][1].parent()
(Vector space of dimension 20 over Ring of integers modulo 401,
 Ring of integers modulo 401)
```

We may also pass classes to the `samples` function, which is useful for users implementing their own oracles:

```
sage: from sage.crypto.lwe import samples, LindnerPeikert
sage: S = samples(30, 20, LindnerPeikert)
sage: len(S)
30
sage: S[0][0].parent(), S[0][1].parent()
(Vector space of dimension 20 over Ring of integers modulo 2053,
 Ring of integers modulo 2053)
```

Finally, `samples()` also accepts instances of classes:

```
sage: from sage.crypto.lwe import LindnerPeikert
sage: lwe = LindnerPeikert(20)
sage: S = samples(30, 20, lwe)
sage: len(S)
30
sage: S[0][0].parent(), S[0][1].parent()
(Vector space of dimension 20 over Ring of integers modulo 2053,
 Ring of integers modulo 2053)
```

Note that Ring-LWE samples are returned as vectors:

```
sage: from sage.crypto.lwe import RingLWE
sage: from sage.stats.distributions.discrete_gaussian_polynomial import _
↳DiscreteGaussianDistributionPolynomialSampler
sage: D = DiscreteGaussianDistributionPolynomialSampler(ZZ['x'], euler_phi(16), 5)
sage: ringlwe = RingLWE(16, 257, D, secret_dist='uniform')
sage: p = samples(30, euler_phi(16), ringlwe)[0][0].parent(); p
Vector space of dimension 8 over Ring of integers modulo 257
sage: assert all(c.parent() is p for b in samples(30, euler_phi(16), ringlwe) for c in b)
```

One technical issue when working with these generators is that by default they return vectors and scalars over/in rings modulo some  $q$ . These are represented as elements in  $(0, q - 1)$  by Sage. However, it usually is more natural to think of these entries as integers in  $(-q/2, q/2)$ . To allow for this, this module provides the option to balance the representation. In this case vectors and scalars over/in the integers are returned:

```
sage: from sage.crypto.lwe import samples
sage: for s in samples(30, 20, 'Regev', balanced=True):
.....:     s1 = list(s[0]) + [s[1]]
.....:     assert all(-401//2 <= b <= 401//2 for b in s1)
```

**class** sage.crypto.lwe.LWE( $n, q, D, secret\_dist='uniform', m=None$ )

Bases: SageObject

Learning with Errors (LWE) oracle.

**\_\_init\_\_**( $n, q, D, secret\_dist='uniform', m=None$ )

Construct an LWE oracle in dimension  $n$  over a ring of order  $q$  with noise distribution  $D$ .

INPUT:

- $n$  - dimension (integer > 0)
- $q$  - modulus typically >  $n$  (integer > 0)
- $D$  - an error distribution such as an instance of `DiscreteGaussianDistributionIntegerSampler` or `UniformSampler`
- `secret_dist` - distribution of the secret (default: 'uniform'); one of
  - “uniform” - secret follows the uniform distribution in  $\mathbb{Z}/q\mathbb{Z}$

- “noise” - secret follows the noise distribution
- (lb, ub) - the secret is chosen uniformly from [lb, . . . , ub] including both endpoints
- m - number of allowed samples or None if no such limit exists (default: None)

EXAMPLES:

First, we construct a noise distribution with standard deviation 3.0:

```
sage: from sage.stats.distributions.discrete_gaussian_integer import DiscreteGaussianDistributionIntegerSampler
sage: D = DiscreteGaussianDistributionIntegerSampler(3.0)
```

Next, we construct our oracle:

```
sage: from sage.crypto.lwe import LWE
sage: lwe = LWE(n=20, q=next_prime(400), D=D); lwe
LWE(20, 401, Discrete Gaussian sampler over the Integers with sigma = 3.000000, and c = 0.000000, 'uniform', None)
```

and sample 1000 samples:

```
sage: L = []
sage: def add_samples():
.....:     global L
.....:     L += [lwe() for _ in range(100)]
sage: add_samples()
```

To test the oracle, we use the internal secret to evaluate the samples in the secret:

```
sage: S = lambda : [ZZ(a.dot_product(lwe._LWE__s) - c) for (a,c) in L]
```

However, while Sage represents finite field elements between 0 and q-1 we rely on a balanced representation of those elements here. Hence, we fix the representation and recover the correct standard deviation of the noise:

```
sage: from numpy import std
sage: while abs(std([e if e <= 200 else e-401 for e in S()]) - 3.0) > 0.01:
.....:     L = [] # reset L to avoid quadratic behaviour
.....:     add_samples()
```

If m is not None the number of available samples is restricted:

```
sage: from sage.crypto.lwe import LWE
sage: lwe = LWE(n=20, q=next_prime(400), D=D, m=30)
sage: _ = [lwe() for _ in range(30)]
sage: lwe() # 31
Traceback (most recent call last):
...
IndexError: Number of available samples exhausted.
```

`__call__()`

EXAMPLES:

```
sage: from sage.crypto.lwe import DiscreteGaussianDistributionIntegerSampler, 
↳LWE
sage: LWE(10, 401, DiscreteGaussianDistributionIntegerSampler(3))([0]).parent()
Vector space of dimension 10 over Ring of integers modulo 401
sage: LWE(10, 401, DiscreteGaussianDistributionIntegerSampler(3))([1]).parent()
Ring of integers modulo 401
```

**class** sage.crypto.lwe.LindnerPeikert(*n*, *delta*=0.01, *m*=None)

Bases: *LWE*

LWE oracle with parameters as in [LP2011].

**\_\_init\_\_**(*n*, *delta*=0.01, *m*=None)

Construct LWE instance parameterised by security parameter *n* where the modulus *q* and the stddev of the noise is chosen as in [LP2011].

INPUT:

- *n* - security parameter (integer > 0)
- *delta* - error probability per symbol (default: 0.01)
- *m* - number of allowed samples or None in which case  $m=2*n + 128$  as in [LP2011] (default: None)

EXAMPLES:

```
sage: from sage.crypto.lwe import LindnerPeikert
sage: LindnerPeikert(n=20)
LWE(20, 2053, Discrete Gaussian sampler over the Integers with sigma = 3.600954 
↳and c = 0.000000, 'noise', 168)
```

**class** sage.crypto.lwe.Regev(*n*, *secret\_dist*='uniform', *m*=None)

Bases: *LWE*

LWE oracle with parameters as in [Reg09].

**\_\_init\_\_**(*n*, *secret\_dist*='uniform', *m*=None)

Construct LWE instance parameterised by security parameter *n* where the modulus *q* and the stddev of the noise are chosen as in [Reg09].

INPUT:

- *n* - security parameter (integer > 0)
- *secret\_dist* - distribution of the secret. See documentation of *LWE* for details (default='uniform')
- *m* - number of allowed samples or None if no such limit exists (default: None)

EXAMPLES:

```
sage: from sage.crypto.lwe import Regev
sage: Regev(n=20)
LWE(20, 401, Discrete Gaussian sampler over the Integers with sigma = 1.915069 
↳and c = 401.000000, 'uniform', None)
```

**class** sage.crypto.lwe.RingLWE(*N*, *q*, *D*, *poly*=None, *secret\_dist*='uniform', *m*=None)

Bases: SageObject

Ring Learning with Errors oracle.

`__init__(N, q, D, poly=None, secret_dist='uniform', m=None)`

Construct a Ring-LWE oracle in dimension  $n=\phi(N)$  over a ring of order  $q$  with noise distribution  $D$ .

INPUT:

- $N$  - index of cyclotomic polynomial (integer  $> 0$ , must be power of 2)
- $q$  - modulus typically  $> N$  (integer  $> 0$ )
- $D$  - an error distribution such as an instance of `DiscreteGaussianDistributionPolynomialSampler` or `UniformSampler`
- `poly` - a polynomial of degree  $\phi(N)$ . If `None` the cyclotomic polynomial used (default: `None`).
- `secret_dist` - distribution of the secret. See documentation of `LWE` for details (default='uniform')
- `m` - number of allowed samples or `None` if no such limit exists (default: `None`)

EXAMPLES:

```
sage: from sage.crypto.lwe import RingLWE
sage: from sage.stats.distributions.discrete_gaussian_polynomial import
↳ DiscreteGaussianDistributionPolynomialSampler
sage: D = DiscreteGaussianDistributionPolynomialSampler(ZZ['x'], n=euler_
↳ phi(20), sigma=3.0)
sage: RingLWE(N=20, q=next_prime(800), D=D)
RingLWE(20, 809, Discrete Gaussian sampler for polynomials of degree < 8 with
↳ sigma=3.0000000 in each component, x^8 - x^6 + x^4 - x^2 + 1, 'uniform', None)
```

`__call__()`

EXAMPLES:

```
sage: from sage.crypto.lwe import DiscreteGaussianDistributionPolynomialSampler,
↳ RingLWE
sage: N = 16
sage: n = euler_phi(N)
sage: D = DiscreteGaussianDistributionPolynomialSampler(ZZ['x'], n, 5)
sage: ringlwe = RingLWE(N, 257, D, secret_dist='uniform')
sage: ringlwe()[0].parent()
Vector space of dimension 8 over Ring of integers modulo 257
sage: ringlwe()[1].parent()
Vector space of dimension 8 over Ring of integers modulo 257
```

`class sage.crypto.lwe.RingLWEConverter(ringlwe)`

Bases: `SageObject`

Wrapper callable to convert Ring-LWE oracles into LWE oracles by disregarding the additional structure.

`__init__(ringlwe)`

INPUT:

- `ringlwe` - an instance of a `RingLWE`

EXAMPLES:

```
sage: from sage.crypto.lwe import DiscreteGaussianDistributionPolynomialSampler,
↳ RingLWE, RingLWEConverter
sage: D = DiscreteGaussianDistributionPolynomialSampler(ZZ['x'], euler_phi(16),
↳ 5)
```

(continues on next page)

(continued from previous page)

```
sage: lwe = RingLWEConverter(RingLWE(16, 257, D, secret_dist='uniform'))
sage: set_random_seed(1337)
sage: lwe()
((32, 216, 3, 125, 58, 197, 171, 43), ...)
```

`__call__()`

EXAMPLES:

```
sage: from sage.crypto.lwe import DiscreteGaussianDistributionPolynomialSampler,
↪ RingLWE, RingLWEConverter
sage: D = DiscreteGaussianDistributionPolynomialSampler(ZZ['x'], euler_phi(16),
↪ 5)
sage: lwe = RingLWEConverter(RingLWE(16, 257, D, secret_dist='uniform'))
sage: set_random_seed(1337)
sage: lwe()
((32, 216, 3, 125, 58, 197, 171, 43), ...)
```

**class** `sage.crypto.lwe.RingLindnerPeikert`(*N*, *delta*=0.01, *m*=None)Bases: `RingLWE`

Ring-LWE oracle with parameters as in [LP2011].

`__init__`(*N*, *delta*=0.01, *m*=None)Construct a Ring-LWE oracle in dimension  $n=\phi(N)$  where the modulus  $q$  and the stddev of the noise is chosen as in [LP2011].

INPUT:

- *N* - index of cyclotomic polynomial (integer > 0, must be power of 2)
- *delta* - error probability per symbol (default: 0.01)
- *m* - number of allowed samples or None in which case  $3*n$  is used (default: None)

EXAMPLES:

```
sage: from sage.crypto.lwe import RingLindnerPeikert
sage: RingLindnerPeikert(N=16)
RingLWE(16, 1031, Discrete Gaussian sampler for polynomials of degree < 8 with
↪  $\sigma=2.803372$  in each component,  $x^8 + 1$ , 'noise', 24)
```

**class** `sage.crypto.lwe.UniformNoiseLWE`(*n*, *instance*='key', *m*=None)Bases: `LWE`

LWE oracle with uniform secret with parameters as in [CGW2013].

`__init__`(*n*, *instance*='key', *m*=None)Construct LWE instance parameterised by security parameter  $n$  where all other parameters are chosen as in [CGW2013].

INPUT:

- *n* - security parameter (integer  $\geq 89$ )
- *instance* - one of
  - “key” - the LWE-instance that hides the secret key is generated
  - “encrypt” - the LWE-instance that hides the message is generated (default: key)

- `m` - number of allowed samples or `None` in which case `m` is chosen as in [CGW2013]. (default: `None`)

EXAMPLES:

```
sage: from sage.crypto.lwe import UniformNoiseLWE
sage: UniformNoiseLWE(89)
LWE(89, 64311834871, UniformSampler(0, 6577), 'noise', 131)

sage: UniformNoiseLWE(89, instance='encrypt')
LWE(131, 64311834871, UniformSampler(0, 11109), 'noise', 181)
```

**class** `sage.crypto.lwe.UniformPolynomialSampler`(*P*, *n*, *lower\_bound*, *upper\_bound*)

Bases: `SageObject`

Uniform sampler for polynomials.

EXAMPLES:

```
sage: from sage.crypto.lwe import UniformPolynomialSampler
sage: UniformPolynomialSampler(ZZ['x'], 8, -2, 2).parent()
Univariate Polynomial Ring in x over Integer Ring
```

`__init__`(*P*, *n*, *lower\_bound*, *upper\_bound*)

Construct a sampler for univariate polynomials of degree `n-1` where coefficients are drawn uniformly at random between `lower_bound` and `upper_bound` (both endpoints inclusive).

INPUT:

- `P` - a univariate polynomial ring over the Integers
- `n` - number of coefficients to be sampled
- `lower_bound` - integer
- `upper_bound` - integer

EXAMPLES:

```
sage: from sage.crypto.lwe import UniformPolynomialSampler
sage: UniformPolynomialSampler(ZZ['x'], 10, -10, 10)
UniformPolynomialSampler(10, -10, 10)
```

`__call__`()

Return a new sample.

EXAMPLES:

```
sage: from sage.crypto.lwe import UniformPolynomialSampler
sage: sampler = UniformPolynomialSampler(ZZ['x'], 8, -12, 12)
sage: sampler().parent()
Univariate Polynomial Ring in x over Integer Ring
```

**class** `sage.crypto.lwe.UniformSampler`(*lower\_bound*, *upper\_bound*)

Bases: `SageObject`

Uniform sampling in a range of integers.

EXAMPLES:

```
sage: from sage.crypto.lwe import UniformSampler
sage: sampler = UniformSampler(-2, 2); sampler
UniformSampler(-2, 2)
sage: sampler() in range(-2, 3)
True
```

`__init__(lower_bound, upper_bound)`

Construct a uniform sampler with bounds `lower_bound` and `upper_bound` (both endpoints inclusive).

INPUT:

- `lower_bound` - integer
- `upper_bound` - integer

EXAMPLES:

```
sage: from sage.crypto.lwe import UniformSampler
sage: UniformSampler(-2, 2)
UniformSampler(-2, 2)
```

`__call__()`

Return a new sample.

EXAMPLES:

```
sage: from sage.crypto.lwe import UniformSampler
sage: sampler = UniformSampler(-12, 12)
sage: sampler() in range(-12, 13)
True
```

`sage.crypto.lwe.balance_sample(s, q=None)`

Given  $(a, c) = s$  return a tuple  $(a', c')$  where  $a'$  is an integer vector with entries between  $-q/2$  and  $q/2$  and  $c$  is also within these bounds.

If  $q$  is given  $(a, c) = s$  may live in the integers. If  $q$  is not given, then  $(a, c)$  are assumed to live in  $\mathbb{Z}/q\mathbb{Z}$ .

INPUT:

- $s$  - sample of the form  $(a, c)$  where  $a$  is a vector and  $c$  is a scalar
- $q$  - modulus (default: None)

EXAMPLES:

```
sage: from sage.crypto.lwe import balance_sample, samples, Regev
sage: for s in samples(10, 5, Regev):
.....:     b = balance_sample(s)
.....:     assert all(-29//2 <= c <= 29//2 for c in b[0])
.....:     assert -29//2 <= b[1] <= 29//2
.....:     assert all(s[0][j] == b[0][j] % 29 for j in range(5))
.....:     assert s[1] == b[1] % 29

sage: from sage.crypto.lwe import balance_sample, DiscreteGaussianDistributionPolynomialSampler, RingLWE, samples
sage: D = DiscreteGaussianDistributionPolynomialSampler(ZZ['x'], 8, 5)
```

(continues on next page)

(continued from previous page)

```

sage: rlwe = RingLWE(20, 257, D)
sage: for s in samples(10, 8, rlwe):
.....:     b = balance_sample(s)
.....:     assert all(-257//2 <= c <= 257//2 for bi in b for c in bi)
.....:     assert all(s[i][j] == b[i][j] % 257 for i in range(2) for j in range(8))

```

**Note:** This function is useful to convert between Sage’s standard representation of elements in  $\mathbf{Z}/q\mathbf{Z}$  as integers between 0 and  $q-1$  and the usual representation of such elements in lattice cryptography as integers between  $-q//2$  and  $q//2$ .

`sage.crypto.lwe.samples(m, n, lwe, seed=None, balanced=False, **kwds)`

Return  $m$  LWE samples.

INPUT:

- $m$  - the number of samples (integer > 0)
- $n$  - the security parameter (integer > 0)
- $lwe$  - either
  - a subclass of *LWE* such as *Regev* or *LindnerPeikert*
  - an instance of *LWE* or any subclass
  - the name of any such class (e.g., “Regev”, “LindnerPeikert”)
- $seed$  - seed to be used for generation or `None` if no specific seed shall be set (default: `None`)
- $balanced$  - use function `balance_sample()` to return balanced representations of finite field elements (default: `False`)
- `**kwds` - passed through to LWE constructor

EXAMPLES:

```

sage: from sage.crypto.lwe import samples, Regev
sage: samples(2, 20, Regev, seed=1337)
[[((199, 388, 337, 53, 200, 284, 336, 215, 75, 14, 274, 234, 97, 255, 246, 153, 268, ↵
